Fam. 10. GRIMMIACEÆ.

Plants tufted in small cushions, or in large lax mats, the stems repeatedly dichotomous. Leaves pluriseriate, ovato-lanceolate, dull green, opaque, lower cells hexagonal or linear, frequently with the inner wall sinuate, upper minute quadrato-rotundate, highly chlorophyllose. Capsule on a straight or arcuate seta, erect, usually equal. Calyptra mitræform, enclosing the whole or part of capsule, rarely cucullate, smooth or sulcate, often pilose. Peristome rarely none, single or double, teeth plane, rarely filiform. Male infl. gemmiform. Inhabiting rocks and stones or the bark of trees.

This great family, including about 700 species, falls naturally into two groups, of which *Grimmia* and *Orthotrichum* are the types; and as in both genera considerable uniformity exists in the leaves, we require to have good fruiting specimens for their satisfactory determination, as the calyptra and seta in *Grimmia*, and the peristome and stomata on the wall of the capsule in *Orthotrichum* are of primary importance.

The species of *Grimmia* have a distinctive aspect in their grey tufts, very often hoary with the white hairpoints terminating the leaves, or they form black fragile patches on the exposed rocks of the higher mountain regions. I have followed C. Mueller, Mitten and Lindberg in uniting *Rhacomitrium* with *Grimmia*, as the linear crenulate leaf-cells regarded as characteristic of the former genus, will be found appearing in many species of the latter.

Orthotrichum also has a peculiar habit which is soon recognized, though the *Schistilium* section of *Grimmia* closely resembles it. The stems are pulvinate or crowded into depressed tufts, dichotomously fastigiate-branched, short and erect, or longer and decumbent or creeping, as is more especially the case in the vast exotic genus *Macromitrium* (which comprises one-third of the whole family), and also in *Schlotheimia* and *Drummondia*. The leaves are often cirrato-crispate when dry, patent or squarrose when moist, hardly ever hoary at point, oblong-lanceolate, entire and papillose, the vaginula ochreate and often pilose, the calyptra mitræform or subcylindric, longitudinally plicate, rarely smooth, the capsule erect, immersed or somewhat exserted, with a tapering neck, costate or striate; peristome very rarely none, simple, of 8 bigeminate or 16 geminate broadly lanc. teeth, very often with an endostome of 8 or 16 cilia alternating with them. The great variability of the peristome has struck all writers, and shows how insufficient this organ is of itself to afford generic characters.

In both divisions transverse sections of the leaves are of the greatest importance in showing their structure, and it will thus be seen that the margin is often thickened by the cells being in two layers, though, in some cases, it is only a single row of cells which is double. Chalubinski's "Grimmieæ Tatrenses" is a splendid monograph of the species found in that part of the Carpathians.

Subf. I. GRIMMIEÆ. Densely tufted, pulvinate, or taller and cæspitose, dichotomous; leaves ovato-lanc., opake, often hair-pointed, upper cells minute, rounded or hexagonal, smooth or weakly papillose, lower elongated or linear and sinuose. Calyptre mitræform, rarely cucullate, smooth or sometimes plicate. Caps. erect, on a straight or arcuate seta; peristome simple, very rarely none; teeth lanceolate, papillose, entire or lacerate or lacunose or in filiform segments.

I. *GRIMMIA* Ehrh.

Beitr. i, 176. (1781).

Mosses growing in small cushions or tufts, generally rooting only at base, innovating below the fertile apex. Leaves crowded in 5—8 rows, patent, lanceolate, usually passing into a white hair, terete-nerved, with the margin narrowly incrassate-limbate, entire, very rarely eroso-denticulate at point, minutely papillose, toward apex quadrato- or hexagono-areolate, opake and often bistratose, at base wider, hexagono-rectangular, linear, sinuoso- or tuberculoso-linear, towards margin rectangular. Calyptre small conic lobate, covering only the operculum, or larger mitræform and lacerate at base, lobato-cucullate or cucullate, smooth or with a rough beak. Capsule erect, cernuous or pendulous, peristome very rarely none, simple, teeth 16, transversely articulated, lanceolate, entire, cribrose, cleft or with filiform legs, papillose, purple, hygroscopic. Inhabiting rocks and stones.—Der. after J. F. C. Grimm, a physician of Gotha.

This genus comprises about 150 species, varying greatly in size from little dense cushions one-third of an inch high, to the great mats of *G. hypnoides*, whose stems attain a length of 8 inches. The dingy colour of the leaves, tipped with long or short white hairs is their most striking feature, and it will be noticed the latter is not due to the excurrent nerve, but to absence of chlorophyl from the leaf point.

CLAVIS TO THE SPECIES.

Sect. I. SCHISTIDIUM. Capsule immersed, wide mouthed; lid falling with the columella attached.

Upper leaves hyaline at point, margins revolute.

In small dense cushions, soft, lurid green.

In laxer cushions, more robust, coarse, fuscous.

All leaves muticous, margins plane.

conferta.

apocarpa.

maritima.

Sect. 2. EUGRIMMIA. Plants short, in rounded cushions, capsule exserted, small-mouthed; teeth lanceolate, cleft or perforated. Leaf cells rounded-quadrata above, elongate or rectangular at base.

Capsule ventricose on one side, immersed, on a very short curved seta.	
Calyptra mitræform, capsule gymnostomous.	<i>anodon.</i>
——— cucullate, capsule peristomate.	<i>crinita.</i>
Capsule symmetric, exserted.	
Seta curved.	
Leaves curled and incurved when dry, subulate.	<i>incurva.</i>
Leaves spirally twisted when dry.	
Hair point long, lower cells sinuose.	<i>funalis.</i>
——— short, lower cells elongate oval.	<i>torquata.</i>
Leaves erecto-incumbent when dry.	
Autoicous.	
Tall, laxly tufted, leaves gradually ending in a longish hair.	<i>decipiens.</i>
Short, densely pulvinate, leaves suddenly hair-pointed.	
Calyptra mitræform.	<i>pulvinata.</i>
——— cucullate.	<i>orbicularis.</i>
Dioicous.	
Leaf-margin plane.	
Leaves not narrowed at base, hair nearly smooth.	<i>Stirtoni.</i>
——— narrowed at base, hair rough.	<i>Muehlenbeckii.</i>
Leaf-margin recurved.	
Tall, robust, naked at base.	
Leaves distant, hair point very short.	<i>Hartmani.</i>
——— dense, hair point longer.	<i>elatior.</i>
Short, slender, leafy to base.	
Basal cells rectangular, not sinuose.	
——— Basal cells short, hair rough.	<i>subsquarrosa.</i>
——— longer, hair smooth.	<i>trichophylla.</i>
Seta straight.	
Calyptra cucullate.	
Short, densely pulvinate.	
Leaves substriate at base, lid conic, obtuse.	<i>alpestris.</i>
——— not striate, lid obliquely rostrate.	<i>montana.</i>
Taller, laxly tufted.	<i>ovata.</i>
Calyptra mitræform.	
Very short, densely pulvinate, capsule pale.	<i>Donii.</i>
Taller, laxly tufted, capsule brown.	
Hair nearly smooth.	
Grey-green, hoary, hair long.	<i>ovalis.</i>
——— Basal cells narrowly rectangular.	<i>microcarpa.</i>
——— sinuoso-rectangular.	<i>elongata.</i>
Fuscous-black, hair very short.	<i>campestris.</i>
Hair rough and spinulose.	

Sect. 3. DRYPTODON. Plants tall, regularly dichotomously branched and fastigiate; teeth more deeply cleft, lower leaf-cells often sinuoso-crenulate.

Calyptra cucullate.	
Leaves lanceolate, rather acute.	<i>atrata.</i>
——— lineal-ligulate, obtuse.	<i>unicolor.</i>
Calyptra mitræform.	
Short, seta straight.	<i>elliptica.</i>
Taller, seta arcuate.	<i>patens.</i>

Sect. 4. TRICHOSTOMUM. Plants tall, robust, with numerous short lateral often fasciculate ramuli; lower leaf-cells narrow, sinuoso-crenulate; teeth cleft into two filiform legs.

Leaves muticous.	
Leaves short, broad, very obtuse.	<i>acicularis.</i>
——— narrower, acuminate.	
Tall and robust, lower cells long, nodulose.	
Upper cells quadrate.	<i>aquatica.</i>
——— sinuose.	<i>fascicularis.</i>
Short, lower cells short, sinuose.	<i>obtusa.</i>

Leaves with hyaline points.	
Hyaline point very short.	
Upper cells rotundate-quadratae.	<i>affinis.</i>
_____ sinuose.	<i>ramulosa.</i>
Hyaline point elongated.	
Leaves smooth.	
Hair point denticulate.	<i>heterosticha.</i>
_____ eroso-serratae.	<i>hypnoides.</i>
Leaves papillose on both sides.	<i>canescens.</i>

Sect. I. SCHISTIDIUM (*Brid.*) Capsule smooth, wide-mouthed, on a very short straight seta, immersed in the perichaetium; lid cupulate, rostellate, falling with the columella attached; calyptra small, mitræform, lobed, scarce covering lid.

I. GRIMMIA CONFERTA Funck.

Autoicous; dwarf, densely tufted. Leaves ovato-lanc., very densely areolate, uppermost with short hair points, margin recurved below. Caps. ovato-globose, leptodermous, fuscous; teeth broadly lanc., orange-red, rimoso-cribrose. (T. XLVI, A.)

Autoicous; pulvinate or in dense small tufts, readily falling apart, dull dark green above, brown or blackish below, radiculose. Leaves when dry erect, appressed, when wet suddenly recurved, then erecto-patent, ovato- or oblongo-lanc., margin recurved below, nerve ending before or at the point, or in the upper leaves excurrent as a short broad hair, areolation very dense, upper cells minute, quadrate, opaque at apex, the basal rectangular; perich. bracts larger, broader, hair-pointed. Calyptra mitræform, lobed, covering lid only. Caps. immersed, leptodermous, fuscous, ovato-subhemispheric, lid convex, acutely apiculate, of same colour as capsule, annulus indistinct, teeth of per-

broad, lanceolate, orange, papillose, rimoso-cribose. Male infl. small, gemmaceous, in the axils of comal leaves.

HAB.—Trap or sandstone rocks; rare. Fr. 3—4.

Arthur's Seat, Edinburgh (*Greville* 1847) !!

VAR. β . *pruinosa* (*Wils.*)

More robust, in blackish tufts. Leaves broader, the upper gradually ending in long smoothish hairs; perich. bracts larger, distinctly papillose. Teeth of per. rufous-orange, more lanceolate, often reflexed against the capsule.

SYN.—*Grimmia pruinosa* WILS. MSS. SCHIMP. Synops. 2 ed. 241.

Grimmia conferta Var. *ineana* BRAITHW. in Journ. Bot. 1872, p. 195. HOBK. Syn. 77.

Grimmia apocarpa Var. *pruinosa* HUSN. musc. gall. 123.

HAB.—Bowling, Glasgow (*McKinlay* 1865) !! Largo Law and Dunbarnie Links, Fife (*Howie* 1863) !! Downe, Perth (*McKinlay*). Cavehill, Belfast, and Rathlin Isl. (*Stewart* 1882) !! Mourne Mtns. (*Lett* 1883).

As will be noticed several good bryologists unite *G. conferta* with *G. apocarpa*, and with some reason as the differences are not very important, still there are several which induce us to keep them apart. These are in *G. conferta* the small size and densely pulvinate habit of growth, dark green leaves, with the apex plane and more minute reticulation, and nerve more prominent at back, the orange rimoso-cribose teeth, which are more fragile and fugacious.

Schimper's var. *obtusifolia* is only a form with blunt-pointed leaves, and *G. pruinosa* may perhaps be regarded as the transition to the next species.

2. GRIMMIA APOCARPA (L.) Hedw.

Autoicous; laxly cæspitose, free from radicles. Leaves broadly lanc., with short hair-points or muticous, the margin strongly revolute. Caps. pachydermous, rufous, teeth deep red, subentire. (T. XLVI, B.)

Autoicous; robust, crowded in lax fuscescent, olivaceous-green or blackish tufts, dichotomously branched, free from radicles. Leaves from an erect base, patent, erect when dry, ovato-lanc. and elongate lanc., concave at base, thence deeply carinate, the margin adpresso-recurved, toothed at the usually hyaline apex, or entire, upper prolonged into a short rough hair; nerve rough above, continued to the hair or vanishing below apex, 5-stratose below; lowest basal cells rectang., then narrow and sinuose, upper rounded. Perich. bracts broader, thinner, with a narrower nerve, hair point shorter or none. Caps. ovate, pachydermous, less concealed in the perichaetium, solid, rufous, lid bright red, mucronato-rostellate, annulus 3—4 rows of small cells; teeth of per. arising below orifice, large, purple red, but little perforated or entire, radiately spreading when dry. Male infl. lateral, gemmiform, bracts ovate, subcucullate.

HAB.—Rocks and stone walls; not uncommon. Fr. 12—3.

Var. *β. alpicola* (Sw.).

Short, more densely tufted, suberect; leaves shorter, broader, ovate-oblong, green, muticous, obtuse, entire, nerve shorter, basal cells laxer; caps. more emergent, calyptra often cucullate, lid long-beaked.

Glaslyn (Holt 1883)! Miller's dale (Holt 1879)! Black Force, Lowgill Fells, Yorks. (Binstead 1886)!! Borrowbank Fell, Loweswater (Waterfall 1885)!!

So variable is this moss, that it is difficult to know where to stop in our series of varieties, which might be extended beyond the number given in Bryol. germ. and yet not include all the forms, which again are connected by intermediate states. Sometimes the leaves are all muticous, broad and obtuse, entire or bluntly serrate at apex, sometimes they run out into longish hairs—the Var. *incana* NEES HSCH.—while the colour varies from green, to fuscous or black. The Var. *pumila* is an elegant little plant, scarcely separable from *G. conferta* but by the stouter build and coarser areolation.

3. **GRIMMIA MARITIMA** *Turn.*

Autoicous; densely pulvinate. Leaves narrowly linear-lanc., muticous, curved and subtortuose when dry; perich. bracts longer, acuminate. Caps. truncate, obovate, lid yellow, convex, rostellate. (T. XLVI, C.)

SYN.—*Grimmia maritima* TURN. Musc. hib. 23, t. 3, f. 2 (1804). SM. Fl. brit. 1199 (1804). Eng. Bot. t. 1645. BRID. Sp. musc. I, 96 (1806); Mant. 32 (1819); Bry. univ. i, 164 (1826). SCHWAEG. Suppl. Grimmia rigida BRID. Bry. univ. i. 768 (1827).

Schistidium maritimum BR. SCH. Bry. eur. fasc. 25—28, p. 10, t. 5 (1845). AONGST. in FR. Summ. Veg. scand. 93 (1846). RABENH. Deutsch. kr. fl. ii, S. 3, 155 (1848). WILS. Bry. br. 151, t. 13 (1855). BERK. Handb. br. m. 243 (1863).

Autoicous; in short densely pulvinate tufts, lurid or blackish green or sometimes yellowish above, fuscous black and interwoven with rufous radicles at base. Leaves densely crowded, erecto-patent when moist, curved and subtortuose when dry, narrowly linear-lanc., muticous, canaliculate-concave, with plane margins; nerve thick, fuscous, vanishing at apex or excurrent in a strong mucro; cells lax and narrowly rectangular at base, minute, indistinct, in 2—3 strata above. Perich. bracts longer, broader, falcate when dry, subpilifero-acuminate. Caps. pale brown, leptodermous, truncate ovate, when dry and empty broadly turbinate; lid yellow, large, convex, suddenly prolonged into a curved beak; teeth ferruginous, broadly lanceolate, remotely articulate, minutely cribrose. Male infl. near the female, gemmiform, bracts broadly ovate, shortly acuminate.

HAB.—Rocks by the sea. West coast of England, Ireland, and Scotland; less frequent on the east side. Fr. 11—12.

This moss grows in dense cushioned mats, and is much more rigid than *G. apocarpa*, with a more prominent perichaetium, and all the leaves muticous. It is found all along the coast from Penzance to Orkney.

Sect. 2. **EUGRIMMIA** C. MUELL. Pulvinate or cæspitose. Caps. on a short, straight, or curved seta, more or less exserted, plicate or smooth, ventricose at base or regular; calyptra small mitræform or cucullate.

* *Curvisetae.*

4. GRIMMIA ANODON Br. Sch.

Autoicous; in small hoary cushions. Lower leaves ovate, muticous, upper ovato-acuminate with long hair-points, concave. Caps. immersed, ventricose at base, gymnostomous. (T. XLVI, D.)

Dioicous; in small soft rounded tufts, dark lurid green above, black below, with fine radicles. Leaves patent-i incurved, strongly curled when

dry, from lanceolate, lineal-subulate, diaphanous or with a short hair at point, at base carinate-concave with recurved margins, thence sub-compligate, cells larger, elongate and hexagono-rectangular at base, sinuoso-quadrata at apex, partly chlorophyllose, partly diaphanous. Perichaetium exserted, bracts from an erect, oblong longly sheathing base, subulate and patent, longer than the capsule.

Caps. on a subarcuate pedicel, cernuous, erect when dry, small, oval, smooth, leptodermous, yellowish; lid convex-conic, obtuse, erose at base, orange-red; calyptora mitrate-subulate, annulus broad of 3 rows of cells; teeth orange-rufous, reflexed when dry, cleft below middle and lacunose. Male infl. terminal, bracts broadly ovate, shortly acuminate.

HAB.—Shady crevices of siliceous rocks; rare. Fr. 4—5.

Bellyside hill and Henhole and in the Bizzle c. fr., Cheviots (*Hardy* 1867) !! Cloch-na-Ben, Kincardine (*Sim* 1868) !! Bach-na-Gairn and Glen Callater (*Fergusson*). Glyders, N. Wales (*Holmes* 1878) !!

The fruit of this moss is very rare, and the plant is very like *Dicranoweissia cirrata*; it may be recognised by the subulate leaves with short hyaline points, and the curly black cushions in which it grows.

7. GRIMMIA FUNALIS (*Schwaeg.*) *Schimp.*

Dioicous; slender, densely cæspitose. Leaves lanc. spirally twisted when dry, upper attenuated into a hair; margins plane. Caps. minute, on a short arcuate seta, ovate, lid conic. (T. XLVII, D.)

Zygodon torquatus LIEBM. in WICKSTRÖM Jahresb. 1839—1842, p. 430. C. MUELL. Synops. i, 682, excl. descr. fr. (1849). HARTM. Skand. fl. 7 ed. 367 (1858).

Dioicous; densely pulvinate, the tufts very convex, soft, fragile, readily falling apart, fine green above, black or rufescent below. Plants erect, slender, 1½ in. high, repeatedly dichotomous, rooting only at base. Leaves erecto-patent, when dry spirally curved round the stem, oblong-lanceolate, lower muticous, upper with a short hair, carinate, the margin straight, erect, nerve thin and channelled, vanishing in the apex, upper

cells punctiform, lower elongate-linear, yellow, the walls incrassate, green, median quadrate, all unistratose. Short jointed filaments, producing globose propagula at upper end, are frequent upon the leaves.

HAB.—Alpine rocks. Fruit unknown.

Ben Lawers, Craig Chailleach, &c: (*Hooker, Greville*)!! Clova mountains. Snowdon (*Wilson*)!! Most of the Irish mountains above 1,000 ft. Falcon clints, Teesdale (*Nowell*)!! White Force and Mazebeck Scarps (*Baker* 1856)!! Hillbell, Westmoreland (*Stabler* 1868)!! Cheviots (*Hardy*). Helvellyn (*Boswell* 1858). Glen Shee (*Ewing* 1884).

This beautiful moss has never been found in fruit, and the supposed fertile specimen of Leibman was due to capsules of *A. lapponicum* growing intermixed. The cable-like twisting of the leaves is still more pronounced than in *G. funalis*, and in the upper part of them they are also curiously inflexed, and then reflexed, but when moist the whole plant is exceedingly soft and flaccid. *G. streptophylla* KINDB. from Kongsvold differs in its wider areolation.

9. **GRIMMIA STIRTONI** Schimp.

Dioicous; in short black tufts. Leaves dense erecto-patent, small, narrowly lanc. upper with smooth longish hair points, margin plane, cells but little incrassate, quadrate, minute and opake toward apex. (T. XLVII, F.)

SYN.—*Grimmia Stirtoni* SCHIMP. Synops. 2 ed. 270 (1876). HOBK. Syn. br. m. 2 ed. 124 (1884).

Dioicous; laxly tufted, $\frac{1}{2}$ in. high, dull black, lurid green at apex, fuscous and radiculose at base. Stems dense leaved, dichotomous and fastigiate branched. Leaves erecto-appressed when dry, erecto-patent and incurved in upper part when moist, small and narrow, concave, the lower lanceolate, muticous, the upper longer, from a more elongate base, lanceolate, ending in a terete nearly smooth hair, one-third length of leaf; margin plane and erect below, thickened above; nerve terete, vanishing at apex; cells at base close, rectangular, soon becoming quadrate, not sinuose, towards apex more incrassate, minute, opake.

HAB.—Basaltic rocks near Glasgow. (*Dr. Stirton* 1866)!

This moss resembles a small state of *G. elongata*, but its structure is more that of *G. pulvinata*, from which however it differs by its much smaller, narrower leaves, with firmer quadrate basal areolation, from the former the non-sinuose areolation and form of leaf-base sufficiently distinguish it.

10. **GRIMMIA MUEHLENBECKII** Schimp.

Dioicous; laxly pulvinate, hoary. L. dense, patulous; elongato-lanc., nerve thick, channelled at back, the hair-point very rough. Caps.

minute, subpendulous, oval, very smooth, lid shortly rostrate, teeth nearly entire. (T. XLVIII, A.)

MILDE Bry. siles. 149 (1869). BRAITHW. in Journ. Bot. 1872, p. 197. HOBK. Syn. br. m. 81 (1873). JURATZ. Laubm. oester.-ung. 161 (1882). BOULAY Musc. Fr. 378 (1884). LESQ. JAMES Moss. N. Amer. 140 (1814).

Grimmia triehophylla var. *Muehlenbeckii* HUSN. Musc. gall. 135 (1887).

Dioicous; laxly pulvinate and vaguely cæspitose, olive-green and hoary above, soft. Stems $\frac{1}{2}$ —1 in. high, erect or procumbent, rooting at base, repeatedly dichotomous. L. densely crowded, erect and incumbent when dry, patulous when moist and bending upwards from the middle, from a longish ovate base, lanceolate, gradually narrowed into a longer or shorter rough hair, concave below, carinate at apex, the margin plane or slightly recurved at the middle, nerve strong, channelled, very prominent above and with two ridges at back; cells above small, roundish-quadrangular, obscure, in 2 strata, at base elongate and somewhat sinuose, 1—3 rows at margin short and hyaline. Caps. on a short yellow subarcuate seta, very small, oval, leptodermous, smooth, brownish-yellow, rugulose when dry, annulus very narrow of 2—3 rows of cells; lid yellow-red with a short beak, teeth red, lanceolate, nearly entire; calyptra 4-lobed.

HAB.—Granite and sandstone rocks in mountains. Fr. 5—7.

Wet rocks near Ballater (Fergusson 1870). Stone in the stream, Kynance Cove, c. fr. (Holmes 1882)!

This moss is very close to *G. trichophylla*, but that species is more robust, the nerve thinner and less prominent at back, with a nearly smooth hair, the cells internally scarce nodulose, the seta longer, capsule twice larger, oblong, subopaque, plicate, firmer, lid rostrate; from *G. pulvinata* it is still more distinct by its dioicous infl., lax olivaceous tufts, taper-pointed leaves and firmer subsinuose areolation. It will probably be detected in many more localities.

II. GRIMMIA PULVINATA (L.) Smith.

Autoicous; glaucous-green, hoary. L. lanceolate with long hairs, recurved at margin. Caps. on an arcuate seta, ovate, striate, rostellate; calyptra mitræform. (T. XLVIII, C.)

Dryptodon pulvinatus BRID. Bry. univ. i, 196 (1826).

Autoicous; in small convex hoary glaucous-green cushions; stems fastigiate-branched, radiculose at base, more dense-leaved toward apex. Leaves appressed when dry, gently recurved when moist, erecto-patulous, lower lanc., acute, muticous, upper oblong-lanc., rather obtuse and carinate, suddenly ending in a long flexuose, serrated hair; margin recurved at base, erect and incrassate above; cells shortly rectangular at base, quadrato-hexagonal above and in 2—3 strata at margin. Seta stramineo-fuscescent, arcuato-deflexed when moist; caps. pendulous,

often depressed among the comal leaves, ovate, leptodermous, brown, distinctly striate, 8-costate when dry, calyptra small, mitræform, lid purple, from a convex base, crenulate at margin, rostellate; annulus of 4 rows of cells, revolute; teeth dark red, longer, slightly perforated, unequally bifid at apex. Male infl. gemmaceous, bracts ovate, concave, muticous.

HAB.—On walls, roofs and rocks; common. Fr. 3—4.

Var. β . *obtusa* (*Brid.*) *Hueben*.

Capsule smaller, on a shorter seta, ovato-globose, the lid obtuse, with a very short blunt point.

SYN.—*Fissidens pulvinatus* var. β . *africanus* HEDW. Sp. musc. 159, t. 40, f. 4—6.

Dryptodon obtusus BRID. Bry. univ. i, 198 p.p.

Grimmia pulvinata var. β . *obtusa* HUEBEN. Musc. germ. 194. SCHIMP. Synops.

HAB.—Exposed rocks.

St. Vincent's rocks (*Thwaites*). Conway castle (*Wilson*). Tickwall, Derby (*Hunt 1863*) !!

This species is generally distributed, and frequent on garden walls, and a form also occurs on dry limestone rocks, with hairs longer than the leaves. The var. β . has been confounded with *G. orbicularis*, but that species differs in the calyptra, the large depressed tufts, and leaves with cells uni-stratose at margin.

12. GRIMMIA ORBICULARIS Bruch.

Autoicous; widely pulvinate, grey, hoary. L. lanceolate, carinate, with long hairs, the margin erect, not incrassate. Caps. on an arcuate seta, subglobose, nearly smooth, with a mammillate lid; calyptra cucullate. (T. XLVIII, D.)

Grimmia mammillaris POECH in musc. bohem. n. 29.

Autoicous; in larger compact swollen hemispherical cushions, falling in pieces when removed, brown at base, olive-green and hoary above. Leaves imbricated when dry, when moist recurved and then erecto-patent, lower small lanc., muticous or with a short hair, upper lanceolate, deeply carinate, running out into a long smoothish hair

which is rather broad at base, nerve thin vanishing at apex, margin slightly recurved, unistratose, cells small roundish-quadrata, at base rectangular, hyaline, becoming quadrate at margin. Perich. bracts narrower, longer, sheathing. Seta short, yellow, arcuato-deflexed when moist, flexuoso-erect when dry. Caps. small, subglobose, faintly striate, bright orange, finally reddish-brown and plicate; calyptra small, cucullate, annulus simple, breaking up, lid small, purple, convex, obsoletely mammillata; teeth pale red, broad and trabeculate below, 3—4 fid at apex. Male infl. gemmaceous, terminal, bracts ovate.

HAB.—Limestone rocks and walls; not common. Fr. 2—3.

Ormeshead and Conway (*Wilson* 1826)!! St. Vincent's rocks, Bristol (*Thwaites* 1843)!! Arthur's seat (*Bevan* 1864). Catdown, Plymstock and Laira (*Brent*). Tamerton-Foliot (*Holmes*). Durdham Downs (*Boswell* 1863). Near Cork (*Dr. Wood* 1859). Between Dublin and Stillorgan (*Moore*). Buckland, Faringdon (*Mrs. Milne* 1863). Milnethorpe (*Barnes* 1865)!! Kinnoul hill (*Dr. B. White* 1866). Paignton, Devon (*Mrs. Holmes* 1885)!! Spelga Mtn., Co. Down (*Lett*).

Growing in much larger patches than the last, and of a darker color, the leaves smaller, narrower, with the margin not incrassate, the capsules smaller, globose, bright red and nearly smooth, and the cucullate calyptra sufficiently distinguish it from *G. pulvinata*.

13. GRIMMIA TRICHOPHYLLA Grev.

Dioicous; laxly pulvinate, yellowish-green. Leaves erecto-patent, narrowly curvato-lanc., with a nearly smooth hair, margin slightly revolute. Caps. on a yellow curved seta, oval angulato-plicate when dry; annulus broad, lid subulato-rostrate. (T. XLVIII, E.)

Campylopus affinis HORNSCH. MSS.

Dryptodon trichophyllus BRID. Bry. univ. i, 771.

Grimmia Schultzii p. p. HUEBEN. Musc. germ. 195 (1833).

Dioicous; laxly pulvinato-cæspitose, soft, bright or yellow-green above, fuscous at base, $\frac{1}{2}$ —1 in. high. Leaves accrescent upward, when moist recurved, then patulous and ascending at point, lower lanc., shortly aristata, upper oblongo-lanc., gradually narrowed into a rather short smoothish or slightly denticulate hair, concave below, carinate above, margin plane above, recurved below but sometimes

only in one wing; cells shortly quadrate above, rectangular and faintly sinuose at mid-base, quadrate at margin. Perich. bracts sheathing to the middle, then suddenly lanceolate, subulate and recurved. Caps. on a longish cygneous pale seta, obliquely decurved, ovate or oblong, 8-costate, pale yellow, finally brown, annulus broad of 4—5 rows of large cells; lid yellow-red, with a short straight beak; teeth longish, red, connivent when moist, erecto-patent when dry, cleft to middle or lanceolate and rimose in the median line. Male plants more slender and simple, infl. terminal, bracts broadly ovate, obtusely pointed.

HAB.—Sandstone and calcareous rocks and walls. Fr. 5—6.

Stoneleigh and Lapworth (*Bagnall*).

A widely distributed and very variable species, known from *G. pulvinata* by its large lax tufts, narrower tapering leaves, and costate capsule, while *G. Muehlenbeckii* differs by the shorter smooth capsule and spinulose hairs, and *G. decipiens* by its autoicous infl., more robust habit and denser foliage. A form occurs on exposed mountain rocks, in dense stunted dark brown tufts, in which most of the leaves are muticous, the upper only having very short hair-points. *G. anomala* SCHIMP. has shorter non-sinuose areolation, with the margin bistratose in 2—7 rows of cells.

14. *GRIMMIA HARTMANI* Schimp.

Dioicous; in tall lax yellowish-green tufts, naked at base. Leaves somewhat secund, oblong-lanceolate, with short smooth or toothed hair-points, carinate, revolute at margin; basal cells rectangular, becoming quadrate at margin, upper rounded-quadrate. (T. XLVIII, F.)

SYN.—*Grimmia incurva* (non SCHWAEGR.) HARTM. Skand. fl. 5 ed. 376 (1849).

Grimmia spheroarpa STIRTON in Scott. nat. ix, 36 (1887).

Dioicous; in large lax dense-leaved tufts, fuscous below, yellowish-green above, blackish at base and deep green above when growing in wet places. Stems procumbent, naked at base, elongate, 2—3 in. long, arcuato-ascending, rigid, with few branches. Leaves when dry loosely incumbent, crisped and incurved, when moist recurved, then divergent and ascending at point, from a small ovate base, elongato-lanceolate,

usually subfalcato-secund, ending in a very short smoothish or bluntly toothed hair-point, carinato-concave at base with the margin more or less reflexed, towards apex acutely carinate with the margin curved outward and 2—3 stratose; nerve smaller at base, irregularly 2—4 ridged at back, running up to the apiculus, bistratose above, 5—stratose towards base, in the young terminal leaves often tipped with globose propagula (1—15), each composed of numerous chlorophyllose cells; cells all incrassate, unistratose, with 1—2 marginal rows bistratose, above small, roundish and opake, below roundish quadrate and sinuose, at base elongate near the nerve, roundish-quadrate and hyaline in several rows at margin. Perich. bracts shorter, from a longish concave base, lanceolate, pointed, with laxer more transparent cells; caps. on a curved, but finally erect seta, longish oval-oblong, smooth, pale brown with a red mouth, annulus of 3—4 rows of small cells, calyptora mitræform, lobed; teeth lanceolate entire or slightly perforated, orange-red, smooth at base; lid conical, subulate, slightly oblique.

Male plants like the female, infl. terminal, inner bracts oval, muticous, antheridia numerous, orange, without paraphyses.

HAB.—Granite rocks and stones in mountain districts.

Dolgelly (*Wilson* 1840). Cardross and Blairgowrie (*Stirton*). Near Conway and Cwm Bychan (*Wilson* 1860) !! Rannoch, Perthshire (*Dr. B. White* 1867). Bridge of Lochay (*Hunt* 1868) !! This fine moss has only twice been found with fruit, first by Hazslinszky on M. Czerbo in Hungary, and recently by Philibert in Corsica; it comes nearest to *G. microcarpa*, but it is at once distinguished by the areolation, as it is also from *G. trichophylla*, as well as by the extremely short hair points.

15. **GRIMMIA SUBSQUARROSA** Wils.

Dioicous; laxly tufted, fuscous and dull green. Leaves patent and subsquarrose when moist, ovato-lanceolate, with a denticulate hair-point, margin recurved, basal cells quadrate hyaline, elongate at margin, upper minute. (T. XLIX, A.)

SYN.—*Grimmia subsquarrosa* WILS. MSS. B. WHITE in Trans. Bot. soc. Edin. ix, 142 (1868). BRAITHW. in Journ. Bot. 1872, p. 196, t. 124, f. 1. HOBK. Syn. br. m. 80 (1873). SCHIMP. Synops. 2 ed. 270 (1876).

Dioicous; in small lax cushioned tufts, fuscous-green above, black at base. Stems $\frac{1}{3}$ — $\frac{3}{4}$ in. high, erect, dense-leaved, dichotomous, the branches short, turgid, a little curved. Leaves erect and appressed when dry, patent, subarcuato-incurved and subsquarrose when moist,

lower lanceolate, submuticous, upper longer and extended into a roughish hair $\frac{1}{3}$ — $\frac{1}{2}$ length of lamina, erect and concave at base with margin recurved, complicato-carinate above, with margin incrassate and erect; nerve solid, semiterete, canaliculate; cells at base hyaline, quadrate, narrow elongate and bistratose in 1—6 rows at margin, above distinct, minute, rotundate-quadratae. Minute globose gonia, in clusters of 2—5, often occur on the surface of the leaves. Male infl. gemmiform, axillary, outer bracts ovato-lanc., acuminate, inner ovate, concave, acute, paraphyses none.

HAB.—Basaltic rocks.

Moncrieff and Kinnoul hills, Perth (*Dr. B. White* 1864) !! Stenton rocks and Balthayock, Perth (*Dr. B. White* 1865) ! Crow road, Campsie (*Hunt* 1866) ! Arthur's Seat and Braid hills, Edinburgh. Dumbuck, Bowling c. fr. (*Dr. Stirton*). Stanner rocks, Radnor (*Rev. J. F. Crouch and Boswell* 1873) !!

Var. β . *Edinensis* (*Ferg.*)

In very short black densely pulvinate tufts; the leaves shorter, less concavo-carinate, less recurved.

HAB.—Arthur's seat (*Rev. J. Fergusson* 1869) !!

The fruit of this moss is reported to resemble that of *G. trichophylla*, but the plant differs from that species in the leaves which are crowded at the apex of the branches, and are more rigid, with rougher hairs and all the basal cells shorter, more quadrate and not at all sinuose, and in the areolation it differs in the same way from *G. Muehlenbeckii*, as well as in the terete, rounded nerve. Perhaps it comes nearest to *G. Hartmanni*, but is far more diminutive, and with different areolation.

16. GRIMMIA DECIPIENS (*Schultz*) Lindb.

Autoicous; robust, laxly tufted, yellow-green, hoary. Leaves elongate-lanc. with rough hairs, carinate, patulous, revolute at margin. Caps. nutant, elliptic, 8 - striate, lid rostrate, cal. mitræform. (T. XLIX, B.)

Autoicous; laxly and irregularly pulvinate or sub-cæspitose, robust, the plants readily falling asunder, dark brown or black at base, yellowish-green passing to gray above. Stems shorter, suberect, or longer, ascending from a procumbent base, repeatedly dichotomous, dense-leaved, with hardly any radicles. Leaves when moist recurved, then patulous and curved upward at point, fuscous-green, long, from an oblong concave base, elongato-lanceolate, carinate above, gradually passing into a very rough hair, the margin here and there reflexed, the perich. bracts sheathing to middle; cells at base linear elongated, rectangular at angles, with 3—4 rows at margin quadrate and hyaline, median longish, apical small, opake, roundish-quadrata, all more or less sinuose; nerve broad, channelled, bistratose. Caps. on a yellowish cygneous pedicel, elliptic and obovate, 8-plicate, pale fuscous with a red mouth; lid $\frac{1}{3}$ length of caps., purple, with a straight beak; calyptora small, many-lobed, annulus broad, revolute; teeth purple, bifid, the legs unequal, erecto-patent when dry. Male infl. gemmaceous, axillar, bracts ovate, acute.

HAB.—Siliceous rocks. Not uncommon. Fr. 4—5.

Clova (*Drummond*). Argyleshire (*Carmichael*). Plymouth and Penzance (*Tozer*). Anglesea, Conway and Breiddin hills (*Wilson 1833*)!! Stenton rocks and Dunsinane (*Dr. B. White 1865*)! By river Cad, Shaugh bridge and Dowerstone rocks (*Holmes 1866*)!! Robin Hood's Bay, Yorks. (*Massee*)! Cader Idris (*Whithead 1879*)! Ben Aan, New Galloway (*McAndrew*). The Scalp, Dublin (*Orr*). Luggielaw, Fairhead and Connemara (*Moore*). Mourne Mtns. (*Lett 1887*)!! Slieve Donard (*Lett 1884*).

Var. β . *robusta* (*Ferg.*)

Stems straight, dichotomous, little branched. Leaves shorter, narrower, with a narrowed yellowish base, the basal cells shorter, firmer, the upper less sinuose smaller and more opake, the hair-point nearly smooth.

SYN.—*Grimmia robusta* FERG. MSS. BRAITHW. in Journ. Bot. 1872, p. 196, t. 124. HOBK. S_n. br. m. 80 (1873).

HAB.—Limestone and granite rocks.

Glen Callater and Glen Phee, Clova (*Fergusson 1868*)!! Gairloch head (*Hunt*)! Near Cardross and Bowling (*Stirton 1864*). Ballater (*Dickie 1869*). Connemara (*Moore 1863*). Dean and Start point, Devon (*Holmes*). Slieve-na-Maddy, Down (*Lett 1885*).

This species is readily known by its robust habit and very dense long leaves with long rough silky points, it is nearly allied to *G. elatior* and also to *G. trichophylla*, but differs from both by the autoicous inflorescence. The Var. *robusta* is a more slender plant, with shorter hair-points, and differs somewhat in the areolation, but this varies considerably, especially in the degree of sinuosity of the cell-walls.

17. GRIMMIA ELATIOR Bruch.

Dioicous; robust, laxly cæspitose. Leaves elongato-lanceolate, from a broader base, deeply canaliculate-concave, with the margin revolute below, gradually attenuated into a smoothish hair. Caps. on a short arcuate seta, oval, 10-striate, lid rostellate. (T. XLIX, C.)

Grimmia funalis * *elatior* HARTM. Skand. fl. 5. ed. 376 (1849).

Dioicous; robust, in broad lax incoherent tufts, black at base, fuscous-green above, canescent; stems dichotomous 1—3 in. high, naked at base, sparingly branched. Leaves subequal, erecto-appressed, when moist strongly recurved, then erecto-patent, very long, from an erect oblong carinate-concave plicate base, with revolute margins, long lanceolate, subcomplicate-carinate, prolonged into a smoothish hair; cells at base 1-stratose, linear rectangular, dilated towards margin, upper rounded-quadrangular, 2—4-stratose at apex, more or less papillose, all slightly sinuose; nerve strong, canaliculate, rounded at back. Perich. bracts larger, erect, laxly areolate. Caps. on a short pale arcuate seta, ovate, 10-striate, when dry oblong and deeply sulcate, pale brown, leptodermous; cal. 5-lobed, annulus of 3 rows of cells, lid rostellate, straight or subacicular; teeth broadly subulate, purple, densely articulated, irregularly cleft and perforated. Male plant more branched, infl. terminal, bracts ovate, shortly acuminate.

HAB.—Quartzose rocks in mountains; very rare. Fr. 3—4.

Clova mountains (Fergusson 1868 ster.) !!

Resembles *G. decipiens*, but is more robust and of a more obscure tint the leaves longer with nearly smooth hairs, the nerve channelled above, 5-stratose. From *G. trichophylla* it differs by the robust habit, upper cells more opaque and bistratose, lower longer and narrower. The branches in *G. elatior* are generally more or less incurved.

** *Rectisetæ*.

18. **GRIMMIA DONII** Smith.

Autoicous; in small green cushions. Leaves elongato-lanceolate, gradually attenuated into a longish hair, the margins plane. Caps. erect, subexserted, oval-oblong, smooth; lid conical, obtuse, annulus small, teeth nearly entire or perforated. (T. XLIX, D.)

Grimmia intermedia FERG. MSS.

Dioicous or autoicous; in compact cushioned tufts, 2—3 in. diameter, glaucescent or dark olive—or blackish-green, more or less canescent, radiculose at base. Leaves erecto-patulous, lower smaller, muticous, comal larger, from an ovate base, lanceolate, gradually or suddenly passing into a smooth decurrent hair, margin plane, slightly incrassate above; cells at base shortly rectangular, with 2—4 rows at margin quadrate and hyaline, the transverse walls more thickened, upper bistratose, opaque, roundish quadrate; nerve narrow, sulcate in front, prominent at back; perich. bracts broader, elongated, semi-vaginant, internal shorter, very narrow. Caps. on an erect straw-colored seta, scarce elevated above the hairs, small, oval or oblong-cylindric, smooth, pachydermous, ferrug.-brown; annulus narrow, of 3 series of cells, variable in distinctness; calyptra large, cucullate, lid conic, subobtuse, rufous, teeth orange-red, conico-subulate, entire or sparingly perforated or cleft at apex. Male infl. terminal or lateral, bracts broadly ovate, obtuse, muticous.

HAB.—On earth in crevices of rocks, very rare. Fr. 4.

Near Ballater (*Rev. J. Fergusson* 1870) !!

Chalubinski's acute observations on this species are quite sufficient to satisfy us that *G. Ungerii* is not specifically distinct from *G. alpestris*, which is truly polyoicous, and the annulus most variable according to the amount and direction of the incrassation of its individual cells; he is also of opinion that hybrids form between *G. alpestris* and *G. Donii*.

Our species closely resembles *G. montana* but that has a larger capsule with acute rostellate lid, and the perich. bracts scarce differ from the comal leaves; the leaves also are more linear towards point, and the hair is longer and roughish. *G. Donii* differs by its small round tufts, small pale capsule and mitræform calyptra.

20. GRIMMIA MONTANA Br. Sch.

Dioicous; in very dense blackish cushions. Leaves erecto-patent, oblongo-lanc., with a long smoothish hair, margin flat, not incrassate. Caps. shortly exserted, erect, small ovate smooth fuscous, lid obliquely rostrate, calyptra large dimidiate. (T. XLIX, F.)

SYN.—*Grimmia montana* Br. Sch. Bry. eur. fasc. 25—28, p. 26, t. 14 (1845). AONGST. in FRIES Summ. veg. sc. 93 (1846). HARTM. Skand. fl. 7 ed. 374 (1858). SCHIMP. Synops. 220 (1860), 2 ed. 264. Dioicous; densely pulvinate, blackish, or dull dark green and canescent at top, fuscous and radiculose at base. Leaves recurved when moist, then erecto-patent, lower small lanceolate muticous, upper oblongo-lanceolate, carinate, flat and erect at margin, running out into a long slightly toothed, decurrent hair; cells above very small, roundish-quadratae, bistratose, opake, at base hyaline quadrato-hexagonal, with 4—6 rows at margin broader and shorter; nerve thick, prominent at back, acutely channelled in front. Perich. bracts larger, sheathing at base, long-haired. Caps. on a short yellow seta, erect oval-oblong, smooth, orange-brown, calyptra cucullate, long-beaked, covering most of caps., annulus of 3 rows of small cells, lid rostrate, $\frac{1}{3}$ length of caps., teeth irregular, often erose at margin, and fisso-cribrose toward point, when dry recurvo-patulous. Male plants more slender, in separate tufts, bracts broadly ovate, acuminate.

HAB.—Porphyry and granite rocks; rare. Fr. 3—4.

Dee-side, Aberdeen (Barker & Ray 1869). Fingle bridge, Devon. c. fr. (Holmes 1877).

Distinguished from *G. ovalis* by the infl., the erect margin of leaf, more prominent nerve, cells opake above, bistratose in middle and longer hair. From *G. alpestris* by the denser more opake areolation of apex, leaves more patent and subulate, short capsule and rostrate lid.

21. **GRIMMIA OVATA** *Web. Mohr.*

Dioicous; deep green, taller, laxly tufted. Leaves lax, erecto-patulous, from an ovate base, lanceolate, with a long hair, cells minute, opake. Caps. large, turgid, ovate, calyptra cucullate, lid obliquely rostrate, teeth broad, trifid. (T. L, A.)

The greatest confusion exists among the older authors between this species and the next, and even Huebener, C. Mueller and others who adopt *G. commutata* quote Hedwig's *Dicranum ovale* as a synonym of it, in spite of the beautiful 5-lobed calyptra figured on his plate. It is clear that *G. ovalis* (HEDW.) must stand for *G. ovata* of most modern authors, and that *G. ovata* WEB. MOHR—collected by them at Carlbergs Allee, Stockholm, although they do not appear to have seen the calyptra—is not the same as Hedwig's *ovalis*, but the type of *G. commutata* HUEBEN. as was suspected by Zetterstedt, and more expressly indicated by Lindberg, who remarks that *G. commutata* is abundant about Stockholm, but *G. ovalis* is scarcely found there, and Weber and Mohr's description of their *G. ovata* “*capsula ovata, pedunculo brevi insidente, opereulo oblique rostrato, per. dentes 16, latiusculi,*” is far more applicable to *G. commutata* than to Hedwig's *G. ovalis*. It is evident then that the original names of the two species, characterized clearly enough when they were established, should be restored, and all the cross references of one to the other had better be avoided. *G. ovata* is distinguished by the dioicous infl., taller stem with more distant leaves, opaque in the upper part, and with very narrow elongated cells near the basal part of the nerve, inflated caps. with long oblique acute beak, cucullate calyptra, and broad trifid teeth of peristome.

22. GRIMMIA OVALIS (Hedw.) Lindb.

Autoicous; robust, laxly pulvinate, blackish green, hoary. Leaves erecto-patent, from an oblong-ovate base, narrowly lanceolate, with a short hair. Caps. erect oval, fuscous, calyptra mitræform, lid short, rostellate, teeth narrow, bifid, cibrose. (T. L, B.)

Breadalbane and Clova mtns. Snowdon. Swithland slate pits, Charnwood forest (*Bloxam*)! Kyloe crags, Northumberland (*Boyd and Jerdon*). Howth and Killiney (*D. Orr.*) Loch Coruisk, Skye (*Dixon 1883*)!

Var. β . *cylindrica* (*Hsch.*) *Hueben*.

Stem erect, with fasciculate branches. Leaves broadly lanceolate, more acuminate, with weaker hair points. Caps. longer, subcylindric.

SYN.—*Grimmia cylindrica* NEES HSCH. Bry. germ. ii, P. I, 161, t. 23, f. 18.

Grimmia ovata ϵ . *cylindrica* HUEBEN. Musc. germ. 183.

HAB.—Near Cherrytrees, Northumberland (*Boyd*)!

Perhaps *G. oralis* most resembles *G. Donii*, but is much more robust, with broader more rigid leaves, the seta longer, with larger and darker capsules. Its difference from *G. ovata* is indicated under that species.

23. GRIMMIA ELONGATA Kaulf.

Dioicous; laxly tufted, brown or black. Leaves patent, elongate lanceolate, lower muticous, upper with a hyaline point. Caps. on a short erect seta, small, ovate; lid conic, obtuse; calyptra with several lobes. (T. XLVII, C.)

SYN.—*Grimmia elongata* KAULF. in STURM Deutsch. fl. II, 15 (1815). FUNCK Moost. 16, t. 11 (1821). BRID. Bry. un. i, 179 (1826). NEES HSCH. Bry. germ. ii, P. I, 166, t. 23, f. 20 (1827). Dioicous; in lax pulvinate tufts, fuscous or black below, olivaceous-green and shortly canescent at apex. Stems slender, elongate, dichotomous, sparingly branched, 3—2 in. high, naked and decumbent at base. Leaves from an erect oblong base, divergent, rather rigid, elongate-lanceolate, lightly recurved at margin, subcomplicate-carinate, muticous, the wings asymmetric, nerve stout excurrent, uppermost with short hyaline points; basal cells linear-rectangular, dilated towards margin, upper quadrate, sinuose, apical minute, bistratose, 1—2 rows at margin 3—4 stratose. Perich. bracts oblongo-lanceolate-acuminate, with short hair points. Caps. exserted on a short straight yellowish seta, small ovate, pale fuscous, smooth, lid conic, obtuse, annulus of 2—3 rows of small cells; calyptora cucullate, lobate, teeth yellow, broadish, cleft or perforated only at apex.

HAB.—Wet alpine rocks; rare and sterile.

Glen Callater and Glen Phee, Clova (*Fergusson* 1868)!

Most of our native specimens are in short dense tufts, largely impregnated with earth and resembling *Andreaea petrophila* in colour.

24. GRIMMIA MICROCARPA (Gmel.) Lindb.

Dioicous; in lax olivaceous tufts. Leaves crowded, patent, ovato-acuminate carinate, with very short serrate hair points, the margins recurved. Caps. minute, elliptic, exserted on a straight seta, cal. mitræform, lid conic, acutely rostrate. (T. XLVIII, B.)

Grimmia microcarpa forma *procera* C. MUELL. Synops. i, 805 (1849).

Grimmia microcarpa LINDB. Act. soc. sc. fenn. X, 558 (1875).

Dioicous; laxly cæspitose, plane, olivaceous or squalid-green, slightly canescent at tips. Stems slender, somewhat elongated, naked below, sparingly fastigiate-branched. Leaves erect when dry, divaricate and patulous when moist, longly lanc., acuminate with acute hoary dentate points, lower muticous, towards base carinate-concave with reflexed margins, above subcomplicate; cells in one stratum, at base sinuoso-rectangular, with a row of broader quadrate ones at margin, above roundish-quadrata with 1—3 rows at margin bistratose, the nerve stout, flattish at back. Perich. bracts sheathing, more laxly areolate, with the nerve vanishing. Capsule on a short yellowish seta, erect, very small, elliptic, light brown, olivaceous when young, leptodermous; calyptra mitræform, nearly smooth at apex, lid acutely rostrate, $\frac{2}{3}$ length of caps., annulus broad, of 4 rows of cells, rolling back, teeth more or less bipartite, red, erecto-patent when dry. Male plant more slender, bracts ovate, acute.

HAB.—Moist alpine rocks. Fr. 4—5.

Ben Lawers (*Greville*)!! Mountains of Connemara and Wicklow (*Moore*). Dartmoor (*Holmes*). Cheesewring, Cornwall (*Brent*). Ingleboro' and Clapdale, Cheviots (*Winch*). Ben Laoigh (*Ewing*). Glen Torridon (*Hunt*).

This species as well as *G. elongata* having straight setæ are removed from the *G. trichophylla* group, to which in their sterile state they would undoubtedly be referred, for *G. microcarpa* has in no form the peculiar ramification of *Trichostomum*, though its sinuose-crenulate cells represent those of that section. *Grimmia affinis* has the greatest resemblance to it, but in *G. microcarpa* the leaves have much narrower points, and the lower cells are shorter and wider.

25. GRIMMIA CAMPESTRIS Burchell.

Dioicous; short laxly tufted, canescent. Leaves broadly oblong-lanc., suddenly running into long rough hairs. Caps. on a straight

seta, elliptic, smooth, lid conic, rostellate, calyptora mitræform. (T. L, C.)

SYN.—*Bryum orbiculare pulvinatum*, *hirsutie canescens*, *capsulis immersis*, var. *capsulis erectis prædita* DILLEN. Hist. musc. 395, t. 50, fig. 65 D—E (1741) et Herbar.

Dryptodon leucophæus BRID. Bry. un. i, Suppl. 773 (1827).

Dioicous; in wide very laxly coherent tufts, dull green, silvery grey above. Stem erect, simple or dichotomous, the branches erect, dense-leaved, subclavate at apex. Lowest leaves minute, triangular-ovate, muticous, thence gradually larger, erecto-patulous, from a broad oblong base, ovato-lanc., suddenly running out into a long very rough hair, decurrent at sides, cymbiform-concave, the margin flat and erect; cells soft, green, roundish-quadrangular, opake, bistratose in upper part, at base next the nerve with 2—6 rows elongate, faintly hyaline, the rest quadrangular; nerve thin and flat. Perich. bracts larger, semivaginant, with lax, rectang. cells, several rows at margin hyaline. Caps. on a pale straight seta, scarce elevated above the hairs, erect, elliptic or tumid-oblong, reddish-brown, rather large, smooth, pachydermous; calyptora mitræform, lobed, annulus of 3 rows of cells, lid conic, subulate or bluntly rostellate, straight, $\frac{1}{3}$ length of caps., teeth 2—3-fid to middle, ciliolate below, rarely subentire, purple. Male plants mixed with female, infl. gemmiform, bracts broadly ovate, with short hairs.

HAB.—Dry granite and basaltic rocks. Fr. 4.

Arthur's Seat, Edinburgh (R. Brown) !! Fairhead, Fife (Arnott). Penzance (Curnow 1878)! The Chasms, I. of Man (Holt 1884)! The Gannel, Newquay, Bolt head and Whitsand Bay (Holmes 1884)! Abbey Craig, Stirling (Lyle). Salcombe (Mrs. Griffiths). Giant's Causeway and Rathlin Island (Moore 1837). Dartmoor (Marquand 1884). Largo Law (Howie 1864).

Readily known by the broad leaves with very rough hair-points, and by the solid rufous capsule, just emergent above the leaf-hairs.

Sect. 3. DRYPTODON (Brid.) Plants taller, in very lax irregular tufts, dichotomously branched, fastigiate. Leaf cells incrassate, their walls more or less crenulate or sinuate. Caps. on a curved or straight seta, smooth; teeth more or less deeply cleft; calyptora mitræform.

26. **GRIMMIA ATRATA** *Mielichh.*

Dioicous; tall, lurid green, dense-leaved. Leaves solid, lineal-lanc., muticous, broadly acute; cells quadrate with crenulate walls. Caps. on a short thick seta, oblong-ovate, with a very short neck; lid obtusely rostellate, calyptra cucullato-mitræform. (T. L, D.)

SYN.—*Grimmia atrata* MIELICHH. in Flora 1819, P. I, 85. HOOK. Musc. exot. ii, 9, t. 100 (1820). FUNCK Moost. 17, t. 12 (1821). SCHWAEG. Suppl. II, P. I, 59, t. 116 (1823). BRID. Dioicous; tall, robust, densely pulvinato-cæspitose, deep black and subtomentose below, lurid green or yellowish at apex; plants erect, densely and uniformly leaved, the branches elongated. Leaves solid, erecto-patent, when dry curved and subcontorted, longly lineal-lanc., straight, carinate-concave, widely acute, muticous, margin here and there reflexed, bistratose in 2 rows, nerve broad, canaliculate, vanishing at apex; cells minute, quadrate, strongly incrassate, the walls punctulato-crenulate, the basal laxer, more elongated, with some pellucid at margin. Perich. bracts semiamplexicaul, cymbiform-concave; caps. on a thick yellow seta, erect or suboblique, ovate-oblong with a very short neck, pachydermous, pale ferruginous, black when old, annulus broad of 3—4 series of cells; lid orange, shortly and obtusely rostellate; teeth with crowded articulations, perforated at apex or cleft to middle, pale ferruginous, recurved when dry. Male plants similar, short, infl. terminal, bracts ovate.

HAB.—Alpine rocks, rare. Fr. 10—11.

Clogwyn-y-Garnedd, Snowdon (*Wilson*, 1826) !! Clogwyn-du-Arddu (*Ralfs*). Glen Callater (*Greville*, 1830) !! Loch Kandor (*Hunt*). Canlochan (*Ewing* 1886).

Differs from *G. elongata* by the absence of hyaline points to the leaves, the incrassate margin and crenulate cell walls, and from *G. elliptica* by the shorter leaves and different lid and calyptra.

27. **GRIMMIA UNICOLOR** *Hook.*

Dioicous; tall, fuscous. Leaves erecto-patent, from an obovate base, linear-lanc., obtuse, muticous, incurved at margin, basal cells rectangular, pellucid at margin. Caps. ovate, lid rostrate, calyptra cucullato-mitræform. (T. L, E.)

SYN.—*Grimmia unicolor* HOOK. in GREV. Scott. cr. fl. iii, t. 123 (1825), Br. fl. ii, 27 (1833). BRID. Bry. univ. i, 182 (1826). HOOK. TAYL. Musc. br. 2 ed. 72, Suppl. t. 3 (1827). WILS. in Eng. Bot. Grimmia atrata SPRENG. (L.) Syst. veg. 16 ed. iv, P. I, 154, p.p. (1827).

Dioicous; in large flat laxly coherent tufts, purple-black below, dull green above. Stems slender, decumbent, naked at base, fastigiate-branched, often with filiform small-leaved ramuli. Leaves patent and erecto-patent, when dry densely imbricated, from an ovate-oblong base, narrowly lineal-lingulate, obtuse, canaliculate-concave, margin erect, nerve scarce prominent at back, dilated at base, vanishing in the apex, cells at base rectang., 2—4 rows at margin quadrate and pellucid, above in 2 strata, gradually minute, quadrate, firm, incrassate, at apex in 2—3 strata, rather fleshy and opake; ramuline leaves obovate, shortly and obtusely acuminate. Perich. bracts broader, sheathing. Calyptra cucullate-mitriform, long-beaked; caps. much exserted, erect or suboblique, oblong or ovate, leptodermous, yellow-brown; annulus broad of 3 rows of cells, lid orange, long-beaked; teeth orange, longish, cleft to middle and lacerate, very densely articulate, erect when dry. Male plants more slender, infl. terminal, bracts ovate.

HAB.—Alpine rocks, rare. Fr. 11—12. Bachnagairn, Clova (*Drummond*) !!

Readily known by the obtuse leaves with incurved margins after the fashion of *Mollia crispula*. The areolation resembles that of *G. ovata*, and is less dryptodontoid than the other species of this section, its affinity to *G. atrata* is however greater than to any other species.

28. GRIMMIA ELLIPTICA (Turn.) Arn.

Dioicous; in rigid blackish depressed tufts. Leaves oblong-lanceolate, suberect, muticous, margin plane incrassate, cells all sinuose, basal very narrow and elongate. Capsule on a thick seta, subglobose, castaneous, hard, lid conico-subulate. (T. L, F.)

SYN.—*Dicranum ellipticum* TURN. Musc. hib. 76, excl. syn. Dill. t. 6, f. 2 (1804). SMITH Fl. brit. 1213, excl. syn. Dill. (1804), Eng. Bot. t. 1901. BRID. Sp. musc. I, 215 (1806). SCHWAEG. Suppl. I, P. I, 184, t. 47 (1811).

Grimmia patens BR. SCH. Bry. eur. fasc. 25—28, p. 18, t. 10 (1845). RABENH. Deutsch. kr. fl. ii, S. 3, p. 163 (1848). C. MUELL. Synops. i, 797 (1849). WILS. Bry. br. 158, t. 19 (1855). DE NOT. Epil. bri. ital. 692 (1869). LINDB. in Act. soc. sc. fenn. x, 556 (1875). JURATZ. Laubm. oester.-ung. 164 (1882). BOULAY Musc. Fr. 375 (1884).

Dioicous; in tall flat fragile olivaceous or fuscous green tufts, blackish and nearly naked at base, 1½—4 in. high, repeatedly dichotomous, with curved branches. Leaves densely crowded, when dry suberect, when moist suddenly recurved, then patent and curved upward, rarely subsecund, elongate lanceolate-acuminata, muticous, carinate-concave below, with the margin revolute up to middle, apex generally subserrate, narrowly carinate, the margin with two rows of cells bistratose; nerve vanishing in the apex, bilamellate at back, the lamellæ bistratose; cells very minute, rounded, the basal angular and yellowish, those next the nerve linear, with several rows next the margin quadrate. Perich. bracts shorter, lanceolate. Caps. bent down on a short yellow cygneous pedicel, elevated a little above perichaetium, oval, smooth, pale fuscous with a red mouth, 8-sulcate when old; calyptra short, smooth, many-lobed; lid red, conico-subulate, straight, annulus 2-seriate, broad, revolute; teeth on an orange basal membrane, divided into two subulate papillose legs cohering here and there, purple, patent-incurved when dry. Male plant more slender and simpler, infl. terminal, bracts convolute, ovate, shortly acuminate.

HAB.—Moist quartzose rocks in mountains. Fr. 4—5.

Frequent in Scotland. Slemish mtn., Antrim, and Powerscourt, Connemara (*Moore*). Galtee-more and Gougaunbarra, Cork (*Carroll*). Brown Willy, Bodmin (*H. N. Dixon* 1886) !! Scandale Glen, Windermere (*C. Barton* 1888) !! Sheepstor (*Brent*).

The wings vanish towards the apex and base of the nerve, but their presence is quite sufficient to distinguish this species from *G. aquatica*, *obtusa*, *elliptica* or *fascicularis*, which have all muticous leaves, while *G. Hartmani*, *elatior* and *decipiens*, which also more or less resemble it, may be known by the hyaline leaf-points.

Sect. 4. TRICHOSTOMUM (*Hedw.*) Taller, dichotomous or irregularly branched, with numerous short lateral ramuli. Leaf-cells towards base longer, with strongly sinuose-nodulose walls. Caps. smooth, on a straight seta; teeth elongate, cleft nearly to base into two filiform legs.

30. **GRIMMIA ACICULARIS** (*L.*) *C. Muell.*

Dioicous; robust, rigid, in lax dark green tufts. Leaves broadly ovate, obtuse, muticous, obsoletely denticulate at apex, recurved at margin. Capsule ovate or subcylindric, lid acicular; teeth cleft nearly to base in 2—3 unequal legs. (T. LI, C.)

- Campylopus acicularis* WAHLEN. Fl. suec. ii, 749 (1826).
- Grimmia acicularis* C. MUELL. Synops. i, 801 (1849).

Dioicous; in lax robust dark green incoherent tufts, blackish at base. Plants 1—3 in. high, rigid, decumbent and naked at base. Leaves appressed when dry, erecto-patent when moist, subsecund at apex, broadly ovate-oblong, canaliculate-complicate, here and there

undulato-plicate, the margin revolute, apex lingulate-obtuse, entire or usually remotely hyalino-dentate; nerve broad, thin, vanishing below apex, cells very small, in one stratum, double at upper margin, roundish at apex, the lower linear, strongly sinuose, at angles laxer, quadrate. Perich. bracts smaller, sheathing. Caps. on a dull red seta, erect, oblong or oblongo-cylindric, short-necked, small-mouthed, dull brown, when old black, annulus broad, lid acicular, half length of caps.; teeth dark red, cleft $\frac{2}{3}$ to base, legs unequal, subulate, connivent when dry. Male infl. terminal, bracts ovate, pointed.

HAB.—On stones by streams in alpine and subalpine districts. Fr. 3—4.

Common in Scotland, Wales, N. of England, and Ireland.

Var. β . *denticulata* Br. Sch.

Plants more slender, the leaves laxer, yellowish green, more laxly areolate, more distinctly toothed at apex.

HAB.—Sandy detritus by streams, occasionally in the lowlands.

31. GRIMMIA AQUATICA (Brid.) C. Muell.

Dioicous; rigid, in lax yellow-green mats. Leaves from an ovate base, gradually lanceolate, obtuse, muticous, quite entire at apex, recurved at margin. Capsule ovato-cylindric, pale fuscous, lid acicular; teeth cleft nearly to base into two legs. (T. LI, B.)

Grimmia aquatica C. MUELL. Synops. i, 800, excl. syn. (1849.)

Dioicous; in lax wide depressed mats, dull or yellow-green above, ferruginous below. Stems elongated, more slender, 1—4 in. high, ascending, repeatedly dichotomous, less rigid, dense-leaved. Leaves when dry laxly incumbent, when moist suddenly recurved, then erecto-patent on all sides, or subsecund, from an oval-oblong base, gradually lanceolate, obtuse, muticous, quite entire, canaliculate, unequally recurved and not incrassate at margin, unistratose; nerve strong, reddish brown, ending in the apex; cells at base long, very narrow, above minute, incrassate, yellow, strongly punctulato-crenulate at margin. Perich. bracts sheathing, thin, nerve shorter. Caps. pseudolateral, on a longish pale brown seta, elongato-elliptic, erect, leptodermous, ferruginous, often scarce overtopping the elongated innovations; calyptra 5-lobed, acicular; lid acicular, straight, red $\frac{2}{3}$ length of caps.; annulus broad; teeth rufous, bipartite, the legs free, entire or partly cohering, perforated. Male infl. terminal, bracts ovate, shortly acuminate.

HAB.—Dripping rocks and waterfalls. Fr. 3—4.

Cronkley Fell, Teesdale (*Nowell* 1851)!! Bleaback Scarr and White Force, Teesdale (*Baker* 1856)! Snowdon (*Wilson*)!! Beddgelert (*Coward* 1858)! Ben Lomond (*Dr. Wood* 1859)! Var. β . *subsimplex* Lindb.

Stems slender arcuate, ascending, naked below, with a few simple arcuate, comose-leaved branches. Leaves shorter, more obtuse, with the margins more widely revolute.

SYN.—*Rhacomitrium obtusum* β . *subsimplex* LINDB. op. c. 543.

HAB.—Glendough (*Orr* 1870, named *R. lanuginosum*).

This moss seems quite distinct in the rounded obtuse points to the leaves, which do not show any trace of a hyaline tip, even in the youngest leaves. It may be known from *G. aquatica* and *fascicularis* by its small size, independent of other characters. M. Corbiere finds it also at Cherbourg.

G. affinis comes nearest to *G. obtusa*, but has always some leaves with hyaline points, and they are also narrower and more acute at upper part, and the cells smaller and less crenate.

33. GRIMMIA AFFINIS (Schleich.) Lindb.

Dioicous; yellowish-green, scarcely hoary. Stems slender elongate, fasciculate-branched. Leaves lanceolate-acuminate, acute with a short

or obsolete hair-point. Caps. elliptic-oblong, narrow at mouth; lid conico-rostrate; teeth short, pale, cleft to base. (T. LI, D.)

HAB.—Damp shady rocks.

Killarney (Wilson)!! Shanslieve (Rev. Mr. Lett 1884)!! High Force, Teesdale (Baker 1856)!!

I have followed Prof. Lindberg in keeping this distinct, though more inclined to retain it as a Var. of *G. heterosticha*. The leaves are longer, with narrower acuminate points, acute and more or less hyaline at tip, and thus it may be known from *G. obtusa*, but the almost obsolete hair-point seems to be the chief difference from *G. heterosticha*, and this may be distinct as a short hair, or it may be reduced to a few hyaline cells.

34. GRIMMIA HETEROSTICHA (*Hedw.*) C. Muell.

Dioicous; in lax depressed rather rigid, dull-green hoary tufts. Leaves lanceolate, gradually attenuated, piliferous; revolute but not incrassate at margin; nerve flat, well defined. Caps. on a straight seta, subcylindric, fuscous; teeth purple, lanceolate bipartite; calyptra rough at apex. (T. LII, A.)

Fr. 359 (1884). LESQ. JAMES MOSS. N. Amer. 149 (1884).

Grimmia heterosticha C. MUELL. Synops. i, 807, excl. varr. (1869).

Dioicous; tufts at first circular, afterwards extended and irregular, blackish-brown at base, above dingy green, grey and hoary; plants in the middle of tuft erect, at margin prostrate and creeping, stiffish, dichotomously branched, sparingly fasciculato-ramulose. Leaves appressed when dry, when wet suddenly reflexed, then erecto-patent or subsecund, from a broadly ovate base, lanceolate-acuminate, running out into an elongate broad decurrent remotely denticulate hair, deeply

canaliculate, the margin revolute, not thickened, nerve flattened, sulcate, well-defined; cells at base obtusely sinuose, narrow and elongated, upper dense, quadrate, very smooth, plane. Perich. bracts shorter, sheathing, with shorter hairs, nerve vanishing above the middle. Calyptora 4—5 lobed, rough at apex; lid conico-subulate, half length of capsule; annulus narrow, yellow; seta straight, reddish-yellow; caps. oblongo-cylindraceous, small-mouthed, pachydermous, tawny-brown, fuscous when old; teeth red, lanceolate, in two unequal filiform papillose legs. Male plant resembling the female, inner bracts broadly ovate, obtuse, apiculate.

HAB.—Quartzose rocks, stones and walls in subalpine districts. Fr. 4.

A frequent moss on moorlands and exposed rocks, and very variable in size, mode of branching and form of fruit, the latter however always more or less cylindric. In its rough rigid habit it much resembles *G. apocarpa*.

35. GRIMMIA RAMULOSA. Lindb.

Dioicous; in lax tufts, stems slender with numerous short branches. Leaves spreading, elongato-lanceolate, acute, with a short serrate hair, cells all elongated and sinuose. Caps. very small, elliptic, lid rostrate. (T. LI, F.)

Grimmia ramulosa LINDB. Musc. scand. 29 (1879).

Rhacomitrium heterostichum Var. *microcarpum* HUSN. Musc. gall. 140 (1887).

Dioicous; in lax depressed tufts, dark brown at base, pale or yellow-green above, lightly canescent; more slender than *G. fascicularis*, flexuose, with short crowded fasciculate obtuse branches. Leaves densely crowded, patulous, variously curved and subsecund at apex, from a longish ovate base with a shallow plait on each side, lanceolate, gradually narrowed into a short toothed hoary point, margin revolute, not thickened at the carinate apex, nerve broad, flat bistratose; areolation of all lamina, sinuose, unistratose, nodulose-linear, very narrow at base, with 1—2 marginal rows hyaline and quadrate. Perich. bracts shorter, sheathing, the nerve vanishing about the middle. Seta short, pale yellow; caps. ovate, elliptic or cylindraceous; very small, leptodermous, yellow, then fuscous with a red mouth; calyptra mitrate, papilloso-scabrous at apex, annulus triple, lid conoid, subulate, $\frac{2}{3}$ length of caps., peristome orange, teeth linear, short, cleft to base into two filiform nodose legs, erecto-patent when dry. Male infl. numerous, inner bracts broadly ovate, shortly acuminate, muticous.

HAB.—Dry mountain rocks. Highlands (Herb. Hooker).

This moss still remains a doubtful native, its claims as such resting solely on the unlocalized specimens in the Hookerian herbarium.

Nearest to *G. fascicularis*, but in that species all the leaves are muticous and rather obtuse with the nerve vanishing below the apex, the capsule also is larger, fuscous and pachydermous. From *G. heterosticha* it is distinguished by the numerous lateral ramuli, diaphanous leaves with the cells of upper part elongated and sinuose, and of the lower elegantly nodulose, those of the margin being 1 and not 2—stratose, and the small pale capsule.

36. GRIMMIA FASCICULARIS (*Schrad.*) C. Muell.

Dioicous; stems elongated, with fasciculate short ramuli. Leaves crowded, incurved or recurved, lanceolate, gradually narrowed, muticous, reflexed at margin. Caps. elliptic, lid long, acicular; teeth long, bipartite. (T. LII, B.)

Trichostomum maritimum BLYTT MSS. HARTM. Skand. fl. 3 ed. 283 (1838).

Grimmia fascicularis C. MUELL. Synops. i, 809 (1849).

Rhacomitrium virescens LINDB. in Act. soc. sc. fenn. X, 68 (1871).

Dioicous; in depressed subintricate tufts, lurid green or yellowish above, fuscous or ferruginous below, rather rigid. Plants often much elongated, prostrate and trailing, naked in the old parts, fasciculate-branched, densely nodoso-ramulose. Leaves densely crowded, patulous, curved upward and backward from an elongate ovate base, narrowly lineal-lanc. muticous, with the margin reflexed, plicate at base, faintly papillose, nerve weak, ill defined, vanishing below apex; cells all elongated and sinuose, 2—4 rows at basal margin hyaline, quadrate. Seta brownish-yellow, thick, calyptro almost wholly papillose, multifid at base; caps. oval or oblong, pachydermous, fuscous, black when old; lid acicular, shorter than caps., crenulate at base, annulus rather broad, teeth purple, long, cleft to base into two filiform nodose legs, erecto-patent when dry. Male plant more slender, with shorter leaves, bracts of infl. broadly ovate, nerveless.

HAB.—Rocks in subalpine districts. Fr. 3.

Readily distinguished by the numerous lateral ramuli, and the perfectly muticous leaves with thin nerve. It somewhat resembles *G. aquatica*, but that species wants the short lateral ramuli, is more rigid with a thicker nerve, and the upper cells of leaf are short and scarce sinuose.

37. **GRIMMIA HYPNOIDES** (L.) Lindb.

Dioicous; in tall wide and lax tufts, black at base, hoary above. Leaves dense, erecto-patent, from an ovate base, long lanceolate-acuminate, the points diaphanous, eroso-serrate. Caps. on a short rough seta, small, ovate, lid long acicular, teeth long with filiform legs. (T. LII, C.)

Grimmia hypnoides LINDB. Musc. scand. 29 (1879).

Dioicous; in tall lax extended swelling grey tufts, with hoary points, brown or black at base. Stems slender, flexuose fragile, ramulose, the

lateral branches longer. Leaves very densely crowded, long, erecto-patent, incurved or secund, especially at apex; thin-nerved, from an ovate base, lanceolate acuminate, with one or more plaits at base, carinate-concave in the upper part, the margin revolute below, apex with a broadly membranous border, excurrent in a hair, its margin flattened, minutely papillose, eroso-subciliate-dentate; nerve bistratose, broad, thin, prominent at back; cells unistratose, quadrate at apex, elongate and very narrow at base, beautifully seriate, eroso-sinuose, walls incrassate, minutely crenulate, one row at the basal wings rectangular and hyaline. Perich. bracts sheathing. Caps. many near the apex, rising from short lateral ramuli, on short rough reddish setæ, small ovato-elliptic, pachydermous, brown; calyptra rough at apex; lid subulate, $\frac{2}{3}$ length of caps.; annulus very broad, revolute; teeth bifid, the legs long equal, filiform, erecto-connivent.

HAB.—Stony heaths, rocks and walls; common in mountain and subalpine districts. Fr. 5—6.

This fine moss is not met with frequently in fruit, which appears to be produced most freely on shaded walls and rocks in the lowlands. The eroso-dentate hair point, which is a most beautiful microscopic object, is quite sufficient to identify the species; Lindberg however has a var. *subimberbis*, where this part is almost wanting, it then approaches *G. affinis*, but the habit and areolation sufficiently distinguish it.

38. GRIMMIA CANESCENS (*Timm*) C. Muell.

Dioicous; in lax yellowish-green hoary tufts. Leaves patulous, ovato-lanceolate, papillose on both sides, with a serrate hair. Caps. on a long smooth seta, ovate, lid long and subulate, teeth very long, with filiform nodulose legs. (T. LII, D.)

Dioicous; laxly cæspitose, the tufts large, plane, yellowish to dingy green, hoary at top, fuscous at base. Stems erect or spreading, 2—4 in. long, with few or many short obtuse branches. Leaves patulous, curved backward and forward, the terminal often secund, from an oblong decurrent concave subsulcate base, narrowly lanceolate, carinate, extended into a flat lanceolate subulate, toothed papillose hair, margin revolute, not incrassate, all surface of lamina densely papillose, nerve very thin, sulcate, vanishing below the hair; cells at base elongated, eroso-sinuose, with several rows at margin quadrate and hyaline, at apex rectangular, sinuose. Perich. bracts sheathing beyond middle, with a papillose nerve. Caps. on a long purple seta compressed when dry and twisted to the left, ovato-elliptic, small mouthed, angular when dry, coriaceous, brown; cal. longly subulate, rough at apex; lid subulate, as long or longer than caps., straight or oblique, annulus broad; teeth long as caps., on a more produced basal membrane, purple, filiform, cleft to base, papillose. Male plant more slender, sparingly branched; inner bracts oblong with a hyaline point.

HAB.—Sandy stony heaths and walls. Fr. 3.

Var. β . *ericoides* (*Schrad.*) *C. Muell.*

Plants shorter, yellowish-grey, lateral ramuli very numerous, nearly equal, pinnately arranged. Leaves shorter squarrose, with shorter hair-points.

Grimmia cricoides LINDB. Musc. scand.

HAB.—Dry sandy places.

Both forms are equally frequent in subalpine districts and delight in the gravelly detritus about the margins of moorland streams. Schimper's Var. *prolixa* is an intermediate form, which with several others often have the hair-point almost obsolete, but the papillose leaves are sufficient to indicate the species. Lindberg regards *ericoides* as the type of the species, and *cunescens* as a variety.

COSCINODON SPRENG.

Einleit. in das Stud. kr. gew. 281 (1804).

Small mosses, growing in dense cushioned tufts. Leaves hair-pointed, resembling those of *Grimmia*. Calyptro large, campanulate-mitræform, multifid at base, plicate, covering greater part of capsule. Caps. half immersed; peristome of 16 lanceolate teeth, arising below orifice, indistinctly articulate, minutely granulose, perforated like a

sieve. Inhabiting rocks and walls.—Der. *κοσκυνον* a sieve and *οδον* a tooth.

A small genus of some 6 species, separated from *Grimmia* on account of the orthotrichoid calyptra. A third European species—*C. Patersoni*—has been described by Rev. J. Fergusson in the Scottish Naturalist, iv, 62 (1877), of which I have seen no specimen.

COSCINODON CRIBROSUS (*Hedw.*) *Spruce.*

Dioicous; pulvinate, dull green, canescent. Leaves ovato-lanceolate, deeply sulcate in each wing; nerved to apex, ending in a smoothish hair. Capsule half-immersed, ovate, lid with a short beak. (T. LIII, A.)

SYN.—*Grimmia cilirosa* HEDW. Stirp. iii, 73, t. 31, A. (1792), Sp. musc. 76 (1801). BRID. Musc. rec. II, P. I, 60 (1798), Sp. musc. I, 100 (1806), Mant. 36 (1819), Bry. univ. i, 174 (1826). ROEHL. Dioicous; in small dense cushions, dull or glaucous green and canescent above, fuscous at base. Leaves ovato- and oblongo-lanc., concave at base, thence deeply sulcate in the middle of each wing, crowded, patulous, nerved to apex, the margin incurved above; the upper ending in a smoothish hair; cells above rounded-quadrata, minute incrassate opake, at base quadrate or rectangular, diaplanous, not incrassate; inner perich. bracts very thin, larger, broader. Caps. just emergent, on a very short straight seta, obovate, the neck defluent into the pedicel, smooth, leptodermous, pale brownish-yellow, when dry, wide-mouthed, cyathiform; ann. simple, persistent, lid cupulato-conic rostellate, red; cal. thin, ochraceous, covering $\frac{2}{3}$ capsule; teeth orange, reflexed when dry, perforated between the articulations with round or elongated ocelli. Male plant more slender, more branched. Infl. in the axils of the branches, bracts broadly ovate, shortly acuminate, paraphyses none.

HAB.—Walls and rocks; rare. Fr. 5—6.

On walls, Coniston (*Prof. Barker 1867*) !! Block of limestone in a bridge at Staveley, near Kendal (*Binstead 1886*) !!

Closely resembling *Grimmia anodon* and *crinita*, but known at once by the plicate leaves, with rectangular leptodermous cells at base.

GLYPHOMITRIUM *Brid.*

Plants short, gregarious or pulvinate. Leaves long, narrow, crisped, opake, areolation minute and quadrate above, laxer and linear or rectangular at base. Capsule exserted. Calyptra mitræform, campanulate, deeply lobulate at base and longitudinally plicate or smooth; per. of 16 lanceolate teeth, entire or bicuspidate or approximate in pairs, papillose or densely trabeculate.—Der. $\gamma\lambda\nu\phi\omega$ to carve, $\mu\tau\rho\iota\omega$ the calyptra.

The three genera here united into one have the closest affinity in the form and structure of their leaves, which in the dry state assume a peculiar hooked position, and *G. Daviesii* only differs in the shorter and broader teeth of peristome, which have a narrow membranous border. About 36 species are known, the majority belonging to the section *Brachysteleum*, represented here by *B. polyphyllum*.

CLAVIS TO THE SPECIES.

Teeth lanceolate, with a hyaline border.	<i>Daviesii.</i>
— cleft into two papillose legs.	
Plants robust, seta straight.	<i>polyphyllum.</i>
— short, seta flexuose, cygneous.	<i>saxicola.</i>

GLYPHOMITRIUM DAVIESII (*Dicks.*) *Brid.*

Autoicous; densely pulvinate. Leaves linear-lanceolate, incurved, entire. Perich. bracts large, convolute. Caps. on a short straight seta, subglobose; cal. covering all caps. contracted and laciniate at base; teeth 16 in pairs, broadly lanc. (T. LIII, B.)

Brachysteleum polyphyllum HORNSCH. Linnaea XV, 127 (1848). C. MUELL. Synops. i, 767 (1849).

Autoicous; plants $\frac{1}{2}$ -2 in. high, erect, crowded in small soft yellow-green cushions, branched from the base. Leaves densely crowded, nearly equal throughout, crisped and spirally involute when dry, erecto-patent when moist, from an oblong plicate base, gradually lineal-lanceolate, acutely carinate, remotely and coarsely serrate below apex or nearly entire, margin revolute up to middle, nerve channelled, vanishing in the apex; cells at base very narrow, elongated, at angles lax, broad, fuscescent, at apex small, quadrate. Caps. aggregated on an elongate straight red seta, longish elliptic, leptodermous, pale brown, lid reddish, subulate, half length of caps., annulus very broad, teeth long, red, cleft to base into two subulate rugulose legs; calyptra roughish at apex. Male infl. axillar, below the female minute, bracts broadly ovate, acuminate, very concave, entire.

HAB.—Siliceous rocks and old walls in subalpine districts. Fr. 3-4.

A common but very beautiful moss, usually fruiting in abundance, its pale red teeth fading away into white at apex. Occasionally it occurs in rough squallid tufts of a black or lurid green colour.

3. GLYPHOMITRIUM SAXICOLA (Web. Mohr) Mitt.

Autoicous; very short. Leaves lanceolate-subulate, subcrispate, entire. Caps. on a geniculate seta, subcylindric, pale, calyptra subulate, 5-lobed, lid subulate, teeth lanc.-subulate, bicrurous. (T. LIII, D.)

A delicate little plant, perhaps often overlooked, and corresponding in distribution somewhat with *Brachydontium*.

Subf. 2. ORTHOTRICHEÆ. Pulvinate, dichotomous and fastigiate, or decumbent and creeping, with erect fertile branches. Leaves lanceolate or ligulate, upper cells rounded, obscure, with verruciform papillæ, lower elongate pellucid. Vaginula surmounted by a membranous tube. Caps. erect, immersed or exserted, often 8-costate, peristome double, outer of 16 pale fleshy teeth, geminate, or 8 and bigeminate, endostome of 8 or 16 cilia alternate with the teeth, rarely gymnostomous. Cal. mitræform, usually pilose, rarely cucullate.

ANŒCTANGIUM Hedw.

Sp. musc. 40 (1801).

Growing in soft swelling yellow-green cushions, interwoven with radicles. Leaves lanceolate, finely papillose. Calyptra cucullate,

small, fugacious; caps. on a short seta, deeply 8-striate, urn-shaped when dry, gymnostomous.—Inhabiting rocks.—Der. *ἀνοικτός* open, *ἄγγειον* a capsule.

A small genus of 7 species, resembling in habit and foliage several of the Tortulaceæ, but differing considerably in the fruit, which has a wide mouth and 8 ribs.

CLAVIS TO THE SPECIES.

Autoicous; leaves oblong-lanc., basal cells leptodermous.
Dioicous; leaves lanceolate, acuminate, basal cells incrassate.

Lapponicum.
Mougeotii.

I. *ANECTANGIUM LAPONICUM Hedw.*

Autoicous; densely tufted olivaceous. Leaves oblong-lanc., erecto-patent, basal cells subquadrate, pellucid. Caps. slightly exserted, oval with a swollen neck, contracted below mouth, lid conic, obliquely rostellate. (T. LIII, E.)

Cylcocarpus lapponicus LINDB. Oefv. vet. ak. foerh. 1862, n. 10.

Autoicous; densely tufted, olive-green or brownish, blackish-brown at base; stem fragile tomentose $\frac{1}{2}$ — $1\frac{1}{2}$ in. high. Lower leaves lanceolate, upper oblong-lanc., patent, curved upward and backward, when dry curled and twisted, keeled, finely papillose, entire, margins plane, the nerve vanishing below the point; cells at base subquadrate, pellucid, above very minute, opaque, chlorophyllose. Perich. bracts narrowed at

base, sheathing, short-pointed, smooth. Caps. on a short yellowish seta, a little exserted above the bracts, oval with a swelling neck rather shorter than the sporangium, fuscous-brown with rufous striæ, when dry and empty strongly contracted below mouth; lid conic with a short oblique beak, calyptra fuscous. Male infl. axillary, gemmiform, often aggregate, bracts broadly ovate, shortly acuminate.

HAB.—Clefts of alpine rocks. Fr. 6—8.

Snowdon (*Wilson*) !! Skye (*Prof. Lawson*) !! Grayrigg forest, Westmoreland (*Stabler*, 1868) !

An elegant moss with beautiful striate capsules sometimes produced in great abundance, and ornamenting the crevices of rocks in most of the Scotch mountains; it is evidently closely allied to *Zygodon* differing principally in its subimmersed fruit.

2. ANOECTANGIUM MOUGEOTII (*Bruch*) Lindb.

Dioicous; in large turgid mats. Leaves long, lineal-lanceolate, acutely carinate, not opake. Caps. stouter on a longer seta, the lid with a subulate beak. (T. LIII, F.)

SYN.—*Gymnostomum Mougicotii* BRUCH MSS. HUEBEN. Musc. germ. 59 (1833).

Barbula Woodii SCHIMP. Synops. 2 ed. 207 (1876).

Anoectangium Mougicotii LINDB. Musc. scand. 29 (1879).

Dioicous; in large soft turgid mats, yellow-green above, ferruginous below, interwoven with scattered radicles. Leaves erecto-patent, longer, lineal-lanc., narrower, acutely carinate, less crisp when dry, nerve stouter, vanishing at apex; cells incrassate throughout, not opake, quadrate, yellowish, nearly smooth, margin revolute at base, entire or with minute crenulations from projecting cells. Perich. bracts sheathing only at base, narrower, longer, gradually acuminate, with the nerve subexcurrent. Caps. on a longer seta, thicker, the neck elongated, lid with a long subulate beak, calyptra straw-coloured, long and narrow. Male infl. gemmiform, bracts ovato-lanceolate.

HAB.—Moist shady rocks. Fr. very rare, 8—9.

Common in mountains. Teesdale (*Spruce*). With fruit, Clova mountains (*Arnott*). Dobb's Linn, Moffat (*Bell* 1861). Campsie (*Stirton* 1863)! Glenballyeman, Cushendall, Antrim, 1 capsule (*Moore* 1863).

Taller than the last, and of a bright yellow-green colour, growing in large patches; the leaves also are much longer and more acuminate, and occasionally are obscurely serrulate towards apex; the capsule long and narrow, with the bands less distinct.

5. PLEUROZYGODON Lindb.

Utkast till en nat. grupp. Eur. bladm. 35 (1878).

Plants erect, densely pulvinate, cæspitose; leaves accrescent upward, lanceolate, densely papillose, the cells minute and opaque above. Perichaetium lateral, of 9—12 sheathing bracts; seta elongated. Calyptra cucullate, subulate rostrate. Caps. ovate with a swollen neck, leptodermous, smooth, gymnostomous; lid obliquely rostrate.—Der. $\pi\lambda\epsilon\nu\rho\alpha$ the side, and $\xi\gamma\delta\sigma\nu$.

Besides the single European species, some 14 others have been described, about equally divided between the Andes and the Himalayas. *Anœct. Hornschuchii* FUNCK, and its Var. *Sendtneri* BR. SCH. belong to a distinct genus *Molendoa* LINDB.

PLEUROZYGODON ÆSTIVUS (Hedw.) Lindb.

Dioicous; in dense matted tufts. Leaves accrescent upward, lanceolate, acute, carinate, papillose. Caps. lateral, leptodermous, ovate-oblong, smooth; lid obliquely rostrate. (T. LIV, A.)

Anœctangium æstivum MITT. in Journ. Linn. soc. Bot. xii, 175 (1869).

Pleurozygodon æstivus LINDB. Utkast, &c., 35 (1878).

Dioicous; in large soft swollen tufts, bright yellow-green above, ferruginous below, radiculose. Stems slender, 1—4 in. high, fragile, dichotomous, fastigiate. Leaves gradually accrescent and more crowded upward, from an erect base, patent, ascending at point, when dry obliquely incumbent and twisted at apex, lanceolate, acute, acutely carinate, very densely covered with short bipartite papillæ; margin plane, minutely crenulate, nerve vanishing below apex, subterete, very prominent at back; cells at base longish rectangular, hyaline, above roundish-quadrangular, small, opake. Perichl. bracts paler, subvaginant beyond the middle, acuminate, smooth; seta $\frac{1}{2}$ -in. high, pale yellow, twisted to right when dry. Caps. erect, small ovate-oblong, with a swelling neck, leptodermous, pale ferruginous with a glossy rufous mouth, smooth when dry and empty; annulus narrow; lid as long or longer than capsule, obliquely rostrate, subulate. Male plants more slender, the infl. gemmiform, bracts ovate, acuminate, faintly nerved.

HAB.—Schistose rocks about streams in mountains. Fr. 8.

Frequent in Scotland, Wales and N. of England. Rare in Ireland; Bantry and Galtee-moore, Tipperary.

Var. β . *pellucida* (*Wils.*).

Plants more robust, densely compact and radiculose, pale yellow-green; leaves longer, broader flatter, with larger cells, which are pellucid and almost free from papillæ.

SYN.—*Anectangium pellucidum* WILS. MSS.

HAB.—Kilblane near Inverary, ♀ (*Wilson* 1836) !!

This moss has taxed the powers of all bryologists to find a satisfactory position for it in our systems, combining as it does various characters pointing to widely different groups. Although the inflorescence proceeds from a lateral bud, it has nothing in common with pleurocarpous mosses, but its habit much resembles that of *Barbula curvirostris*, as also does the fruit, and the leaves are equally akin to those of *Anect. Mongeotii* in structure. The var. *pellucida* is a larger plant in every way, with laxer leaves, and may be distinct.

6. ZYGODON Hook. Tayl.

Musc. brit. 70 (1818).

Plants dichotomous, fastigiate branched, crowded and interwoven with radicles. Leaves spathulate-lanc., very chlorophyllose above, hyaline at base. Caps. on an elongated pedicel, oval-oblong, with a soft swelling neck, less distinctly striate; peristome single or double

rarely none, the teeth resembling those of *Orthotrichum*. Calyptra smooth, cucullate. Inhabiting trees and rocks.—Der. ζυγός a yoke, ὀδούς a tooth.

Between 60 and 70 species of this genus have been described, about half of them being natives of S. America. The peristome agrees in structure with that of *Orthotrichum*, the lid differing in being obliquely rostrate, and the calyptra cucullate.

CLAVIS TO THE SPECIES.

Nerve excurrent in a mucro.	<i>Stirtoni.</i>
— vanishing below point.	
Leaves entire, plants rather short.	
Peristome none.	<i>viridissimus.</i>
— present.	
Autoicous, in dense tufts with pale radicles.	<i>Forsteri.</i>
Dioicous, in loose tufts with red radicles.	<i>conoideus.</i>
Leaves denticulate at apex, plants tall.	<i>gracilis.</i>

I. ZYGODON STIRTONI. Schimp.

Dioicous ; leaves dense, erecto-patent, elongate lanceolate, the wings often unequal at apex ; nerve thick, prominent at back, excurrent in a smooth-pointed mucro ; cells at base ovali-rectangular smooth, above rounded, papillose. Caps. subglobose. (T. LIV, B.)

SYN.—*Zygodon humilis* HUNT MSS. 1867.

Zygodon Stirtoni SCHIMP. MSS. STIRTON in Trans. bot. soc. Edin. xi, 75 (1871). HUSN.
Musc. gall. 148, t. 42 (1887).

Zygodon aristatus LINDB. Act. soc. sc. fenn. x, 542 (1875).

Dioicous ; in short dense tufts, dull yellow-green above, fuscous and radiculose at base, dichotomous. Leaves dense, erecto-patent, straight, elongato-lanceolate, wings often terminating unequally at apex, the margin crenulate with minute papillæ ; nerve yellow, thick, rounded and very prominent at back, excurrent as a very thick, subterete pungent fragile awn ; cells strongly incrassate, basal ovali-rectang. or quadrate, smooth, the rest rounded, chlorophyllose, each with several minute acute papillæ on the surface. Perich. bracts like the leaves but with a shorter awn, and the cells in the lower half laxer and more elongated ; caps. on a yellowish elongated seta, erect, leptodermous, subglobose-pyriform with a small mouth, gymnostomous, faintly striate when dry ; lid rostrate.

HAB.—Rocks and limestone walls, especially near the sea. Fr. rare, 4.

Roadside near Barmouth c. fr. (Wilson 1863) ! Coast at Elie, Fife, c. fr. (Howie 1864) !! Buxton (Hunt 1867) !! Arbroath and Troup head, Forfar (Fergusson 1864) !! Menmuir, c. fr. (Anderson). Bowling and Campsie (Stirton 1865). Ben Lawers and Killin (Stirton 1867). Limestone wall at Plymouth (Holmes 1867) !! Cromaglow and

Muckross on beech (*Lindberg* 1873). Derry, Ireland, on a sycamore c. fr. (*J. H. Davies* 1885)!! Kilroot and Rathlin island, Antrim (*Stewart* 1880)!! Gordale Scar and Malham (*Holt* 1885)!! Chee Tor and Monksdale (*Holt* 1886)!! Rushen Abbey, I. of Man (*Holt* 1884)!! Annalong, Co. Down (*Rev. H. Lett.*). Penmaen Rhos, Colwyn (*Holt* 1889)!!

This is certainly distinct from the next species, being of much firmer texture, with sub-erect leaves and nerve excurrent to a variable extent, the lamina often ending unsymmetrically on each side of it; the capsule also is rounder with a small mouth. It occasionally grows intermixed with *Z. viridissimus* and its variety, and thus becomes an occupant of tree trunks.

2. *ZYGODON VIRIDISSIMUS* (*Dicks.*) *Brown.*

Dioicous; in small lax bright green tufts. Leaves patent, recurvo-squarrose, lineal-lanc., acuminate, nerve narrow, vanishing below apex. Caps. on a longish seta, leptodermous, oval-oblong with a short neck, striate at mouth, lid rostrate. (T. LIV, C.)

Zygodon Nowellii SCHIMP. Synops. 2 ed. 297 (1876). HOBK. Syn. br. m. 2 ed. 130 (1884).

Dioicous; in wide crowded tufts, brownish or blackish-green above, reddish-brown at base. Stems 1—3 in. high, rigid, repeatedly divided, with innovations at short intervals, and fuscous branched radicles at the lower leaf-axils. Leaves crowded, when moist subrecurvo-patent, when dry laxly incumbent, lower narrowly elliptic-lanc., upper from a concave oblong base, narrowly lanc., arched backward, acutely carinate, the wings patent from the middle, waved, minutely papillose, at apex irregularly erosio-serrate or only with 3—6 irregular distant repand teeth, nerve semiterete, narrow, subcanaliculate in front, hispidulous at back, vanishing just below apex or slightly excurrent; upper cells very small, rounded and well-defined, more or less chlorophyllose, basal oblongo and hexagono-rectangular, smaller towards margin, pachydermous, diaphanous. Perich. bracts similar; vaginula oblong, paraphysate, seta stout rufous, only 3 times length of capsule which is oblongo-cylindric, suberect, somewhat asymmetric, castaneous, 8-striate, costulate when dry, lid conico-rostellate pale red, calyptra long, rostrate, annulus large, of 3 rows of cells; teeth pale, rather broad, 8 bigeminate,

cleft at apex, like those of *Z. conoideus*, articulations numerous, minutely vermiculate, cilia 8, partly adhering to the teeth. Male plants in separate tufts, more slender, infl. terminal, stoutly gemmiform, bracts ovate, acuminate, the nerve thin and vanishing, antheridia and paraphyses numerous.

HAB.—Calcareous rocks and walls rare. Fr. 5—6.

Middlehouse, near Malham Tarn (Nowell 1856)!! and c. fr. (Whitehead 1879). Old limestone walls, Heselton gill, Litton dale c. fr. (Nowell 1866)! Ingleboro, in the ascent from Clapham (West 1876)!! Connemara, Ireland (Wilson).

This species has quite a different aspect from the other European forms, resembling most the Mexican *Z. campylophyllus* C. MUELL. The fruit is rare with us, but has been found in good condition in the Tyrol.

7. ORTHOTRICHUM HEDW.

Musc. frond. ii, 96 (1788).

Growing in round cushions on trees, rocks or walls. Leaves lanceolate, generally recurved at margin, not dilated at base, imbricated or twisted when dry, minutely papillose, cells punctiform and chlorophyllose above, hyaline and elongate below. Capsule on a short pedicel, as long or longer than the ochreate vaginula, immersed or exserted above the leaves, 8—16 striate, the striæ alternating with the teeth, prominent or forming ribs when dry, very rarely none. Teeth of peristome 32, geminate or bigeminate, formed of one series of quadrate cells; endostome of 8 or 16 cilia, filiform, articulated, alternate with the teeth, often rudimentary or abortive. Calyptra mitræform, lobed at base, conico-campanulate, plicate, naked or covered with straight filiform ramenta.—Der. *oρθος* straight, *θριξ* hair.

About 120 species of *Orthotrichum* have been described, but judging by a study of our native species, it is to be feared that many of these must sink into synonyms. The great difficulty in dealing with the genus is the great uniformity in the habit of the species, and, with a few exceptions, the little variation to be met with in the form and structure of the leaves. These are more or less imbricated when dry, but when wetted, quickly become recurved from the base and then gradually erecto-patent, in shape oblongo-lanceolate, or sublinear, the point obtuse, acute or acuminate, very rarely piliferous, the margin usually revolute, the upper cells incrassate, usually bearing coarse or fine, cleft or conical papillæ. The vaginula is smooth or hairy and is crowned by a little membranous tube enclosing the pedicel, named the ochrea or vaginal tube, this pedicel is usually very short, so that the fruit is

seldom exserted above the upper leaves ; the caps. is symmetric, erect, oval or subcylindric, almost always striate with 8 or 16 vittæ or bands, which after sporing, produce on the ripe dry capsule as many ridges and furrows, these bands or ribs consist of darker and larger cells than the intermediate tissue, arranged in 2—5 vertical series, and their walls, especially the lateral, much and often irregularly thickened. The peristome is very rarely wanting, and is extremely variable, the teeth consist of 32 flat lanceolate processes, generally united in pairs (geminate), or in fours (bigeminate), and are covered with papillæ, but sometimes with very minute sinuous lines, and when dry are erect, spreading horizontally, or reflexed against the capsule ; very often an endostome is also present in the form of 8 or 16 cilia, consisting of 1 or 2 rows of cells, opposite to the ribs of caps. and therefore alternate with the teeth ; too much value however must not be fixed upon them, as they are sometimes imperfect or abortive. The calyptra is campanulate or conical, longitudinally plicate, more or less covered with straight hair-like processes, or sometimes quite smooth.

A very important character has been discovered in the two forms of stomata found on the lower part of the capsule, and applied by Lindberg in 1866 to divide the genus into two sections ; these are 1. *Superficial*—(termed *phaneropores* by Milde, *stomata normalia* by De Notaris, *stomata nuda* by Venturi), —which are seated in the cuticle only, and the two stomatic cells are thus naked and visible ; 2. *Immersed*—(*cryptopores* of Milde, *stomata sphincteriformia* of De Notaris, *stomata periphrastra* of Venturi),—these are sunk in the capsule-wall and the two stomatic cells more or less covered by a circle of projecting cuticular cells. In order to obtain a proper knowledge of the form of the capsule, it should be soaked in water for some hours, and to observe the stomata the base of the caps. should be cut off, the fruit slit up on one side, the spore sac removed, and the pericarp with the cuticular side upward, spread out in water on a slide and covered with glass ; a power of 300 will be required. Dr. Carrington added largely to the knowledge of our native species in the Phytologist for 1858, and Dr. Venturi, of Trient, who has for years paid unremitting attention to the genus, first in Hedwigia for 1871—3, and recently in Parts 5—6 of Husnot's Muscologia gallica, has given masterly descriptions of all the European species, which leave little to be desired.

CLAVIS TO THE SPECIES.

Stomata superficial.

Leaves obtuse, with plane margins.

obtusifolium.

— more or less acute, with recurved margins.

Shawii.

Peristome simple.

Peristome and endostome present.

striatum.

Capsule without ridges.

— with ridges and furrows.

Autoicous, cilia 8.

Capsule striate nearly all its length.

Caps. short, brown ; calyptra yellow.

rufescens.

— long, narrow, pale ; cal. pale greenish.

affine.

Capsule faintly striate at upper end.

speciosum.

Dioicous, cilia 16.

Lyellii.

Stomata immersed.		
Upper leaves with diaphanous hair-points.		<i>diaphanum</i> .
— without diaph. hair-points.		
Leaves obtuse.		
Leaves round at point, with small crowded cells.		<i>rivulare</i> .
— apiculate, with lax rounded cells.		<i>Sprucei</i> .
Leaves more or less acute.		
Teeth of per. striolate vertically, with short basal lamellæ.		
Capsule immersed or emerging.		<i>cupulatum</i> .
— much exserted.		<i>anomalum</i> .
Teeth of per. papillose, without lamellæ.		
Neck of caps. shrivelling into a cup, enclosing the pedicel.	<i>Schimpéri</i> .	
— defluent into the pedicel.		
Vaginula hairy.		<i>stramineum</i> .
— smooth.		
Capsule immersed.		
Caps. oval-oblong, calyp. campanulate,		
naked.		<i>pallens</i> .
— cylindric, cal. conic, with few hairs.	<i>tenellum</i> .	
Capsule exserted.		<i>pulchellum</i> .

Sect. 1. *GYMNOPORUS* *Lindb.* Stomata on wall of capsule superficial.

* Dioicous; leaves obtuse with plane margins.

I. **ORTHOTRICHUM OBTUSIFOLIUM** (*Schrad.*)

Dioicous; in small yellowish-green cushions, with short turgid branches. Leaves imbricated, broadly ovate with the margin erect, obtuse and hyaline at apex. Caps. immersed, oval-pyriform, with the neck longer than sporangium, and 8 weak bands; stomata superficial; teeth 8, bigem.; calyptora naked, covering the capsule. (T. LV, A.)

Weissia obtusifolia ROTH Tent. Fl. germ. iii, I, 218 (1800).

Dorcadion obtusifolium LINDB. Musc. scand. 29 (1879).

Dioicous; in small dense cushioned tufts, pale or yellow-green above, fuscous at base; stems $\frac{1}{2}$ —1 in. high, with a few turgid branches. Leaves closely imbricated when dry, quickly spreading when wet and then becoming straight, ovate-oblong, concave-carinate, obtusely rounded, slightly hyaline and minutely serrulate at point, plane at margin, often bearing small oblong septate gemmæ on the

surface, papillose at back; cells at base quadrate at margin, more elongated in the middle, gradually becoming rounded upward, with strongly incrassate walls and a large projecting papilla which is sometimes bifurcate; nerve vanishing below apex. Perich. bracts broader, thinner, subvaginant, sulcate. Caps. yellow, deep orange at mouth, just immersed, oval or pyriform with the neck longer than sporangium, abruptly narrowed at base into a very short pedicel, contracted below the mouth and furrowed when dry, bands 8, not prominent, composed of two rows of quadrate cells; stomata superficial; calyptora conic-campanulate, naked, brown paler at margin, covering the sporangium, roughish at apex, lid conic with an orange point. Teeth of per. 8 bigeminate, orange, obtuse at point, more or less lacunose in the divisural line, densely and finely papillose; cilia 8, shorter than the peristome, yellow, of two rows of papillose cells. Male plants with the female or in separate tufts, more slender.

HAB.—On elms and oaks, rare and barren.

Near York (*Wilson* 1856). Near Cheltenham (*Beach* 1851). Chipping Campden and Mickleton, Glos. (*Kirk* 1857)!! Stratford-on-Avon and Harbury (*Bagnall*)!! Wytham wood, Oxon. (*Boswell*). Near Buckingham (*Holmes* 1884)!! Kettering (*Dixon* 1885). Pencombe, Perrystone and Hentland, Hereford (*Rev. A. Ley* 1886).

This moss has not been found with fruit here, but is readily known by the subclavate branches with broad obtuse leaves, erect at margin.

Another closely allied species (*O. gymnostomum* BRUCH) is found with this on the continent and should be looked for here, especially as Dr. Venturi informs me that a specimen was sent to him by Jaeger from the collection of M. Sickenerger labelled, "England, Yorkshire." In this species the capsule is oblong and gymnostomous, the leaves ligulate, involute at margin, with rhomboidal cells.

** Endostome of 8 slender smooth or punctate cilia, sometimes wanting.

2. ORTHOTRICHUM RUPESTRE. Schleich.

Autoicous; laxly pulvinate, dichotomous. Leaves oblong-lanc., revolute at margin. Caps. immersed, oblong, 8-striate, gradually defluent into the pedicel, teeth 8, bigeminate, pale, papillose rugulose, cilia 8; calyptora campanulate, fuscous, hairy. (T. LV, B.)

SYN.—*Orthotrichum rupestre* SCLEICH. Crypt. helv. exs. Cent. III, n. 24 (1806). SCHWAEG. Suppl. I, P. II, 27, t. 53 (1816). BRID. Mant. 110 (1819), Bry. univ. i, 279 (1826). Orthotrichum affine β . *rupestre* BRID. Sp. musc. II, 7 (1812).

Orth. flaccum DE NOT. Epil. 301.

Dorcadion rupreste LINDB. musc. scand. 29 (1879).

Autoicous; more or less densely tufted or pulvinate, fuscous, olivaceous or yellowish-brown, rather rigid when dry; stems erect, 1—2 in. high, sometimes longer and ascending, more or less branched. Leaves oblong-lanc., suddenly or gradually acuminate, straight, imbricated when dry, recurvo-patent when moist, carinate, the margin recurved or revolute to apex, nerve vanishing toward point, or reaching it; cells mostly unistratose, narrowly rectangular at base, rounded or angular above, papillæ minute, simple or bifurcate. Caps. immersed or emergent, pale yellow, fuscous when old, oval or oblong, truncate when dry and empty, not contracted below mouth, gradually defluent at base into the pedicel; bands 8, rarely with intermediate ones, stomata superficial, annulus persistent, of 2—3 rows of depressed cells; lid conic, apiculate; calyptra plicate, campanulate, ferruginous, with numerous yellow hairs. Teeth 8, splitting into 16, each half lacunose or cleft, pale yellow, erect when dry, surface papillose or with faint sinuous lines, cilia 8, yellowish, long as teeth, sometimes wanting. Vaginula naked or hairy, male infl. lateral, bracts ovate, rather obtuse.

HAB.—Rocks and walls in subalpine districts. Fr. 7—8.

Var. β . *rupincola* (Funck.) Hueben.

Densely crowded, subpulvinate; leaves straighter, capsule smaller, emergent, calyptra less hairy.

Doreadion rupestre β. *Sturmii* LINDB. Musc. Scand. 29.

Orth rupestre δ. *Sturmii* JURATZ. Laubm. oester.-ung. 201.

HAB.—Basaltic rocks.

Luggielaw, Wicklow, Fairhead and Seven Churches (Moore 1857). Bowling (Hunt 1865)!! Largo Law, Fife (Howie 1869)!! Knocklayd, Antrim (Stewart 1882)!! On trees, Glen Ogle, Perth (Horn 1887)!!

O. Sturmii is certainly not separable from *O. rupestre*, for the bistratose cells in the upper part of leaves are by no means uniform, and we find numerous transition forms. The typical plant is plentiful about the bases of all the Highland mountains, perhaps nowhere finer than around Schiehallion.

3. **ORTHOTRICHUM SHAWII** Wilson.

Autoicous; in short green tufts. Leaves lanc.-acuminate, nerved to apex, the cells unistratose. Capsule oval-oblong, with 8 faint bands below the mouth; teeth 16, reflexed when dry, white papillose, cilia none; calyptra hairy. (T. LV, C.)

SYN.—*Orthotrichum orneum* WILS. MSS.

Orthotrichum Shawii WILS. MSS. (non DE NOT.). SCHIMP. Bry. eur. Suppl. Fasc. 1—2 (1864); Synops. 2 ed. 314 (1876). HUNT in Mem. Lit. Phil. soc. of Manch. 3 Ser. iii, 236 (1867). HOBK. Syn. br. m. 90 (1873). VENT. in HUSN. Musc. gall. 165, t. 46 (1887).

Autoicous; in small lax deep green tufts, $\frac{1}{2}$ —1 in. high. Leaves laxly incumbent when dry, spreading from an erect base when moist, lanceolate acuminate, deeply carinate, nerved nearly to apex, recurved at margin; cells small, rectangular and hyaline at base, denser and roundish quadrate above, unistratose, the papillæ not prominent. Vaginula naked, calyptra pale and glossy, with a reddish brown tip and a few thin hairs; caps. immersed, oval-oblong, leptodermous, pale yellow, with 8 scarcely conspicuous bands below the mouth where it is slightly contracted, rounded at base and passing abruptly into a very short pedicel; stomata superficial.

Peristome of 16 whitish lanceolate teeth, gaping in the divisural line, densely papillose, reflexed against the capsule, cilia none; lid conic, rostellate, with a red margin. Male infl. small, axillar, the bracts ovate, lingulate, obtuse.

HAB.—Ash trees on the lawn of Kilkerran Castle, Dailly, Ayrshire. (*J. Shaw*, June, 1860)!!

This rare species has some resemblance in the capsule to *O. striatum*, but is much smaller, and the capsule always shows some traces of bands, but no cilia. Perhaps its natural position is near the var. *Sturmii* of *O. rupestre*, and Venturi conjectures that it may be a hybrid between *rupestre* and *striatum*; the Italian specimens referred to it by De Notaris, belong according to Venturi, to *O. rupestre* var. *Franzonii*.

4. **ORTHOTRICHUM AFFINE Schrad.**

Autoicous; tall, laxly pulvinate. Leaves lanceolate, acuminate, with revolute margins, cells rounded, incrassate, with prominent papillæ. Caps. emergent, oblongo-elliptic, defluent into a longish neck, 8-striate; teeth 8, bigeminate, cilia 8, filiform. Calyptra conical. (T. LV, D.)

Autoicous; in loose pulvinate tufts, tall, yellowish or dull green, repeatedly dichotomous. Leaves more or less strictly imbricated when dry, quickly recurved and patulous when wetted, coarse, lanceolate acuminate, acute, nerve vanishing at point, margin reflexed all the length; cells at base unequal, quadrangular-oblong, above rounded, sub-oval or subhexagonal, incrassate, papillæ simple or bifurcate, prominent. Caps. emergent, leptodermous, pale yellow when empty, oblong or oval-cylindric, defluent at base into a longish neck, passing into a very short

pedicel; when dry contracted, pale brown, deeply sulcate, wall with 8 narrow bands the length of sporangium, of 2—4 rows of quadrang. cells, with incrassate lateral walls, stomata superficial; teeth of per. pale yellowish; 8 bigeminate, sometimes partially cleft in the divisural line or perforated at summit, papillose or with the papillæ forming anastomosing vermicular lines, when dry recurved on the outer wall of capsule, cilia 8, filiform, of two series of cells. Lid conic, apiculate, yellow with a red margin. Calyptra conic, not inflated, covering the caps., light olive-green with the apex black, slightly hairy, rarely almost naked; vaginula smooth. Male infl. lateral, bracts ovate, rather obtuse.

HAB.—Trees in damp shady places, sometimes on walls. Fr. 6—7.

Var. β . *rivale*. Wils.

Stems loosely tufted; leaves succulent, lurid green, broader, very obtuse, lax when dry. Calyptra narrow, lurid green: caps. exserted oblong-pyriform, less tapering into the pedicel, not so contracted when dry, with broader ribs of 4—5 rows of cells, cilia 8 shorter.

SYN.—CARRINGT. in Trans. Bot. soc. Edin. 1858, p. 54, Phytol. 1858, p. 573.

HAB.—On trees by streams.

Congleton Cloud (Wilson 1854). Laskill, Yorks. (Baker 1854). By the Wye, Cheedale (Whitehead 1878)!! By the Ribble at Horton (Ashton and Whitehead 1878)!! Millersdale (Holt 1884)!! Dailly, with *O. Sprucei* (Shaw 1861)!

Var. γ . *fastigiatum* (Bruch) Hueben.

Tufts smaller, denser and turgid, deep green; leaves oblong-lanceolate, shorter, with very small papillæ and laxer cells; caps. stouter, darker brown, less tapering, urceolate when dry, the ribs broader, teeth and cilia shorter, the latter wider, papillose; calyptra wider, straw-coloured, ferruginous.

HAB.—On trees in open fields, especially in limestone districts.

Greta bridge, Yorks. and Scale hill, Sussex (Borrer). Newcastle (Winch). Bolton Abbey and Malham (Nowell). Dailly, Wemys Bay, Dunoon, Inverkip and Callander (Dr. Wood)! Nant-y-Belan (Wilson 1833). Conway (Palgrave). Frodsham, Cheshire (Wilson 1845)!! Thirsk and Laskill, Yorks. (Baker).

This variable species may be known by the thin pale capsule, cylindric and fusiform when empty, and always with narrow ribs. The var. *rivale* by its obtuse leaves approaches *O. rivulare*, but the stomata and larger leaf-cells at once distinguish it.

5. **ORTHOTRICHUM SPECIOSUM** *Nees.*

Autoicous; in large loose tufts. Leaves oblongo-lanceolate, acute, revolute at margin. Caps. emersed, cylindraceous with a long neck, pale, with 8 faint bands in the upper half; teeth 8 bigeminate, pale, reflexed, cilia 8, papillose, calyptora hairy. (T. LVI, A.)

SYN.—*Orthotrichum striatum* HEDW. Stirp. ii, t. 36, f. 1—3 (1788).

Dorcadion speciosum LINDB. Musc. scand. 28 (1879).

Autoicous; tufts loose, more or less dense, yellow-green, fuscous at base, the stems branched, 1—1½ in. high. Leaves laxly imbricated when dry, patulous or slightly recurved when moist, oblong-lanceolate, more or less longly acuminate, acute, all margin revolute, nerve nearly reaching apex; cells at base elongato-rectang., with unequally incrassate walls, gradually passing upward into rounded strongly incrassate cells with one or more simple or bifid papillæ. Caps. emersed or emergent, leptodermous, faintly narrowed below the mouth, passing gradually into the pedicel by a longish neck, cylindric or rarely oval-oblong when dry, smooth, greenish, afterwards pale yellow, more or less furrowed; stomata superficial; bands 8, faint or at most marked by a short row of large quadrangular longitudinal cells; teeth 8 bigeminate, rarely cleft in median line, pale, densely papillose, opake, revolute, with the upper part applied to capsule wall, cilia 8 white, large papillose, sinuose at margin. Lid conic with red border. Cal. conic-campanulate, blackish at apex, covering all caps., and with yellow hairs. Male infl. axillar, gemmiform, the bracts ovate, acuminate.

HAB.—Trees in alpine districts, not common. Fr. 7—8.

Montrose (Reid). Forfar (Drummond). Corrie Moolzie, Braemar (Wilson 1836)!! Kinnordey (Sir J. Hooker). Henfield, Sussex (Spruce). Hurst & Tilgate (Mitten). Settle, Yorks. Aviemore (Whitehead 1876)!! Ballater (G. Davies 1867)! Stockton forest, Yorks. (Spruce 1843)!

Larger than *O. affine*, with less dense leaves, the capsule longer and cylindraceous, pale yellow, the bands indistinct; the branches also are longer, and the seta is variable in length, but the capsule is always more exserted than in *O. affine*, the bands being most evident after sporing; the leaves are frequently of a reddish-brown colour with areolation varying in density.

*** Endostome of 16 broad papillose cilia, erose at margin, of two rows of cells.

6. ORTHOTRICHUM STRIATUM (L.) Hedw.

Autoicous; in irregular tufts. Leaves lanceolate, acuminate with a revolute margin. Caps. immersed, oval, without striæ, per. of 16 geminate teeth, circularly revolute when dry, but not touching wall of caps., cilia 16, broad, erose at margin; calyptora conic, deeply striate. (T. LVI, C.)

VENTURI in Musc. gall. 165, t. 45 (1887).

Dorcadion striatum LINDB. Musc. scand. 28 (1879).

Autoicous; tufts irregular or more or less dense, with fastigiate branches, ramulose, erect or decumbent, 1—3 in. long, radiculose at base, deep or yellowish green. Leaves loosely imbricated when dry, spreading when moist, when wetted strongly recurved and then quickly erect, lanceolate or longly attenuate, the margin recurved or revolute to the point; cells unistratose, basal smooth, quadrangular, flexuose, passing gradually up into roundish, strongly incrassate with simple papillæ. Caps. immersed, smooth, without any striæ, pale yellow, oval or oblong, rounded at base and suddenly narrowed into a very short

pedicel, contracted slightly below the mouth, stomata superficial; peristome of 16 teeth with a strongly marked divisural line and short articulations, transversely striolate, densely papillose, pale yellow, opake, when dry circularly revolute but not touching the caps. wall except with the points, endostome of 16 cilia, erect, broad, erose at margins, yellowish, papillose, of two rows of cells; lid conic elongate, red at margin; calyptra conic, straw-coloured with a dark tip and many yellow hairs; annulus double persistent. Male infl. gemmiform, lateral axillar.

HAB.—On trees, not uncommon. Fr. 4—5.

Linnæus assigns the following character to his *Bryum striatum*, “antheris sessilibus sparsis, calyptis striatis sursum pilosis,” and it is evident his name referred to the calyptra and not to the capsule, as was assumed by Schimper and his followers, and therefore in our opinion the name *striatum* must be retained. The species may be known from *O. affine* by its smaller size, dense leaves, smooth capsule and 16 cilia.

7. ORTHOTRICHUM LYELLII. Hook. Tayl.

Dioicous; in tall lax tufts. Leaves patent and recurved, longly lanc., acute, bearing rufous, clavate gemmæ. Caps. oval-oblong, striate, decurrent in a longish neck; teeth 16, pale, revolute, cilia 16, broad, appendiculate. (T. LVI, B.)

SYN.—*Orthotrichum Lyellii* HOOK. TAYL. Musc. brit. 76, t. 22 (1818). GREV. in Mem. Wern. soc. iii, 355. HOOK. GREV. Edin. Journ. Sc. i, 124 (1824). GRAY Nat. arr. br. pl. i, 747 (1821). BRID. Dioicous; in large lax tufts 1—4 in. high, dull yellowish-green above, fuscous and naked at base, the stems with subarcuate branches, soft, erect or ascending. Leaves incumbent and spreading when dry, strongly patent and recurved when moist, undulate at margin, from an oblong base very longly lanc., narrow, acute, the margin recurved above the base, plane in all the rest of the leaf, the surface bearing many rufous septate, clavate or branched protonemal processes; nerve vanishing in the point, which is sometimes slightly toothed; cells at base smooth, elongated, subflexuose, above small rounded or suboval,

strongly incrassate, with prominent conical papillæ. Caps. immersed, yellowish-brown, oval-oblong, 8-striate, decurrent at base in a longish neck, slightly narrowed below mouth, when dry and empty elongate, deeply sulcate; stomata few, superficial; teeth 16, geminate, pale, revolute when dry, cilia 16, rather broad, appendiculate, papillose, rufous; lid pale, nearly conical; calyptora conic, elongate, with yellow hairs. Male infl. lateral, axillar.

HAB.—Trunks of old trees, not unfrequent. Fr. 7.

This fine moss may be readily known by its large size and long subsquarrose leaves, and is scattered throughout the whole kingdom, for I have found it in fine fruit at Virginia Water, and at Finlarig, Killin, as well as in Yorkshire and intermediate districts. Dr. Spruce found a marked form by the Ouse near York in 1843, with rigid, closely appressed leaves.

Sect. 2. *CALYPTOPORUS* *Lindb.* Stomata immersed in the wall of capsule and more or less covered by some of its epidermal cells.

* Upper leaves hair-pointed, cilia 16.

8. *ORTHOTRICHUM DIAPHANUM* *Schrad.*

Autoicous; in small loose cushions, hoary at top. Leaves oblong-lanc., with acuminata hyaline points. Caps. emerging, oblong, suddenly contracted at base, teeth 16, cilia 16, cal. campanulate, nearly naked. (T. LVI, D.)

O. aristatum TURN. Musc. hib. 100, t. 9, f. 2. SM. Fl. brit. 1265.

O. heterophyllum and *O. pilosum* P. BEAUV. Prodr. 80 (1805).

Autoicous; in small irregular dark green tufts, hoary at top. Leaves imbricated when dry, erecto-patent when moist; soft, oblong-lanc., termi-

nated by a lanceolate membranous point, colourless, denticulate at margin, and composed of narrow elongate cells, margin revolute, nerve vanishing in the apiculus; cells at base quadrangular, elongate, above rounded and hexagonal, rather large, with very small obtuse papillæ. Caps. emergent, pale yellow, oblong, not contracted below mouth, leptodermous, when dry oblong-obovate, when moist suddenly contracted at base into a short pedicel, ridges 8, of two rows of indistinct quadrangular cells; stomata numerous, immersed, with elevated border-cells. Calyptra naked or nearly so, campanulate, thin, greenish-yellow, brown at point, 8-plicate; lid short, conical. Peristome pale yellow, of 16 geminate teeth more or less cleft at point, papillose, long, recurved when dry, cilia 16, filiform, hyaline, papillose. Male infl. terminal on a short branch.

HAB.—Trunks of trees, walls, and old pales. Fr. 4.

This little moss is easily overlooked, as it only grows in small tufts, and somewhat sporadically; it may be recognized at once by the hyaline points to the leaves.

** Peristome teeth striolate, with erect vertical lamellæ at base; cilia none or rudimentary.

9. ORTHOTRICHUM CUPULATUM Hoffm.

Autoicous; in coarse dull green tufts. Leaves oblong lanceolate. Caps. immersed, oval-oblong with 16 ridges, calyptra campanulate, hairy; teeth 16, each with four basal lamellæ. (T. LVI, E.)

Autoicous; in loose dull green or olivaceous tufts, $\frac{1}{2}$ —1 in. high. Leaves imbricated when dry, recurved when moist, oblong-lanc., rather obtuse, recurved at margin; cells above very small, subhexagonal or rounded, incrassate, with 1—2 simple or rarely bifurcate papillæ, basal rectangular, smooth; nerve vanishing below the apex, channelled above. Caps. immersed, rarely exserted, pale olivaceous brown, oval-oblong, rounded at base and suddenly narrowed into a very short pedicel, urceolate when dry, with 16 ridges, the alternate ones shorter, or rarely with 8 only, each composed of 2—3 rows of quadrate yellow incrassate cells; stomata immersed, the border cells elevated, not covering all the stomatic cells. Annulus of 2—3 rows of compressed cells; lid shortly apiculate, pale yellow, orange at margin. Peristome simple, pale yellow, rarely with traces of cilia, teeth when dry spreading horizontally, never recurved, 16 geminate, with 4 basal lamellæ to each, reaching to second or third joint, or sometimes much higher, surface traversed by faint sinuose longitudinal lines. Calyptra swollen, campanulate, plicate, naked or with some hairs, brownish or ochraceous, rusty at apex. Male infl. pseudolateral, bracts ovate, obtuse.

HAB.—Rocks and walls in limestone districts. Fr 4—5.

Var β . *nudum* (*Dicks.*)

Tufts more laxly pulvinate, deep green. Caps. partly or entirely exserted, attenuated at base into a longer narrower neck, teeth more distinctly striolate, with the external appendages more developed. Calyptra more conical, naked or with a few hairs.

SYN.—*Orthotrichum nudum* DICKS. Crypt. fasc. IV, 7, t. 10, f. 13 (1801). SM. Fl. brit. 1268. Eng. Bot. t. 1325. TURN. musc. hib. 97, BRID. Sp. musc. II, 12; Mant. III. VENT. in HUSS. musc. gall. 161, t. 45.

Brachytrichum saxatile ROEHL. Deutsch. fl. iii, 47 (1813), Ann. Wett. ges. iii, 194.

Orthotrichum aureum MART. Fl. cr. erl. 77, t. 2, f. 2 (1817).

Dorcadion anomalum LINDB. Musc. scand. 28 (1879).

Autoicous; tufts rather dense, olivaceous green or almost black. Stems $\frac{1}{2}$ —1 in. high, erect, dichotomous and fastigiate. Leaves imbricated when dry, recurved when moist and then becoming patent, lanceolate, upper elongated, more or less suddenly acuminate, acute; nerve stout, vanishing below apex, cells in a single layer, basal rectang. smooth, the walls unequally thickened, gradually passing upward into hexagonal and rounded, with slightly incrassate walls and simple papillæ; margin recurved below. Caps. generally exserted above the perichaetium, sub-cylindric or oval-cylindric, slightly contracted below the mouth, attenuated at base into a conical neck, passing more or less suddenly into the pedicel; stomata immersed, bands 8 or 16, long as sporangium, orange-brown, the 8 principal of 2—3 rows of quadrate cells with strongly thickened lateral walls, the alternate bands fainter, sometimes almost imperceptible, annulus persistent, double; peristome simple, pale yellow, teeth erect when dry, 8 bigeminate, or 16 geminate, longitudinally striolate, each tooth at base with four little striolate lamellæ, reaching the second joint or extending upwards in fragments; cilia none or rudimentary. Calyptora conic-campanulate, covering the caps., the hairs rusty-yellow. Lid conic-apiculate.

HAB.—Stones and trap rocks; rare. Fr. 5.

Trap rocks at Aberdour, Fife (*Luckman* 1860)!! Arthur's Seat (*Dr. B. White* 1862)!! Largo Law, Fife (*Howie* 1865)!! Abbey Crag, Stirling (*Lyle*). Conway Castle (*Wilson*). Armagh (*Adm. Jones*). By the Dodder at Sallygap (*Orr*).

Var. β . *cylindricum* Schimp.

Plants larger. Caps. longer, more exactly cylindric, more exserted, with 8 longer bands of larger more coloured cells, 8 cilia more or less well developed, teeth 8, imperfectly divided. Leaves longer, narrower, with a stronger nerve.

SYN.—*Orthotrichum anomalum* Sm. Fl. brit. 1265, Eng. Bot. t. 2696. TURN. Musc. hib. 94. HOOK. TAYL. Musc. br. 72, t. 21. HOOK. Fl. scot. 137. GRAY Arr. Br. pl. i, 745. WILS. Bry. brit. 177, t. 21.

HAB.—Limestone rocks and walls, not uncommon.

Frequent in the Buxton and Craven districts. Ormeshead (Wilson). Lake district (Whalley 1865). Castle Howard (Spruce 1841). Litton (Whitehead 1879) !! Sussex. Devon (Holmes). Cheshire (Whitehead). Tulloch, Blair-Athol (Braithwaite 1887) !! Bruton and Wilmcote, Warwick (Bagnall). Ireland (Dr. Moore). Chapel-en-le-Frith and Castleton, Derby (Holt 1882) !!

There is no doubt that these two mosses only constitute a single species, for the presence or amount of development of the intermediate bands is very variable and affords no reliable character. Bridel tells us that he changed the name *anomalum* to *saxatile*, because there are other anomalous species! So much for Nature daring to offend the laws of humanity. I find no mention of *saxatile* in Dr. Wood's paper cited by Schimper, and as that name has been applied to both forms, it is also better to drop it altogether. See also Dr. Wood's Supplemental notes in Phytologist V, 26 (1861).

*** Peristome teeth papillose, without lamellæ; cilia smooth, 8 or 16.

II. ORTHOTRICHUM RIVULARE Turn.

Autoicous; blackish green, growing in water. Leaves oblong-linguiform, obtuse, apiculate. Capsule immersed, pyriform with 8 broad bands; teeth reflexed when dry, cilia 8, filiform, often with 8 shorter intermediate ones; calyptora naked (T. LVII, B.)

SYN.—*Orthotrichum rivulare* TURN. Musc. hib. 96, t. 8 (1804). Sm. Fl. brit. 1266 (1804). Eng. Bot. t. 2188. BRID. Sp. musc. II, 3 (1812), Mant. 111 (1819), Bry. univ. i, 292 (1826). SCHWAEG. Suppl. Autoicous; in loose blackish-green tufts, floating or submersed. Stems naked below, dichotomous and fasciculate branched, $\frac{3}{4}$ — $1\frac{1}{2}$ in.

high. Leaves laxly imbricated when dry, quickly recurved from the base when wet and again becoming spreading, oval at base, oblong-linguiform, rounded at apex and obtuse or very shortly apiculate, sometimes slightly toothed, revolute at margin in the lower half, recurved in upper half to apex; nerve very prominent at back, faintly channelled in front, ending suddenly below the summit; cells at base hyaline quadrate with thin walls, passing gradually into roundish, with very small papillæ. Caps. semi-immersed, yellow, contracted below the mouth when dry, 8-costate for all its length, when moist oval or oval-oblong, suddenly contracted into a very short pedicel; annulus persistent, of 4—5 rows of small angular cells, the bands reddish-yellow of 4—7 series of quadrate cells, with strongly incrassate lateral walls, stomata immersed, with the border cells very prominent. Teeth 8, orange, bigeminate, when dry recurved against the capsule, more or less perforated in the median line, very densely and finely papillose; cilia 8, filiform, long as teeth, yellow, faintly papillose, often 8 intermediate cilia more or less developed. Vaginula with colourless paraphyses. Lid conic, apiculate. Calyptra conic-campanulate, naked, lurid greenish with a blackish apex, plicate to base. Male infl. at base of fruiting branch.

HAB.—On rocks and stumps in water; not common. Fr. 4—5.

On the Cart and Calderwood burn (*Don*). Congleton, Cheshire and Nant-y-Belan, N. Wales (*Wilson*) !! Eskdale below Ainsthorpe and Ripon (*Baker* 1858). Corwen (*Boswell* 1859). Hurstpierpoint (*Mitten*) ! Cheviots (*Hardy*). Glenprosen (*Fergusson*). Keswick (*Hunt* 1862). Callander (*McKinlay* 1864). R. Teign at Fingle bridge (*Brent*). R. Dee, Llangollen (*Nowell* 1862) !! Ribble at Horton (*Whitehead* and *Ashton* 1878) !! The Wye, Cheedale (*Whitehead* 1878) !! Glasgow (*Lyle* 1842). Lowood, Windermere (*Hunt* 1867) !! In the Dargle, Wicklow and Cork (*Taylor*). Glenavy river, Antrim (*Stewart* 1880) !!

This fine but dingy moss is more frequent with us than in any other part of Europe, and by the obtuse leaves is most allied to the next species. From *O. affine* Var. *rivale* it is readily separated by the stomata.

12. ORTHOTRICHUM SPRUCEI Mont.

Autoicous; short, sparingly branched. Leaves erecto-patent, oblong-spathulate, obtuse, apiculate, margin nearly plane. Caps. pyriform with 8 broad striæ, calyptra campanulate, naked, teeth 8, bigeminate, cilia 8 or 16. (T. LVII, C.)

Syn.—*Orthotrichum Rogeri* Var. ARNOTT in litt.

Orthotrichum Sprucei MONTAGNE MS. SPRUCE in Lond. J. Bot. 1845, p. 186. C. MUELL. Synops. i, 699 (1849). BR. SCH. BRY. EUR. fasc. 42, t. 2 (1849). WILS. BRY. BR. 184, t. 45 (1855). SCHIMP. Synops. 273 (1860), 2 ed. 338. BERK. Handb. br. m. 225 (1863). HORN. Syn. br. m. 93 (1873). VENTURI in HUSN. Musc. gall. 177, t. 48 (1887).

Autoicous; in dark lurid green, sparingly branched tufts. Leaves soft and succulent, rather distant, erect and loosely imbricated when dry, erecto-patent when moist, obovate-spathulate, rounded at point and muticous, the upper with a very small apiculus, revolute at margin at the base, and then recurved to some distance below the summit; cells at base quadrangular, elongated next the nerve, passing gradually up into large rounded or angular, smooth or faintly papillose ones, nerve slender, lost below point. Perich. bracts longer, narrower, sulcate, with a shorter nerve, sometimes with a long piliform point. Caps. immersed, soft, pale, fuscous when old, oval pyriform, with a long sulcate neck, broadly 8-striate, stomata immersed; annulus of two rows of compressed cells, teeth 8, bigeminate, yellowish, reflexed when dry, densely and finely papillose, cilia 8, shorter than the teeth, yellow and finely papillose, sometimes 16; lid conic, rostellate. Calyptra campanulate, greyish green, naked smooth, apex and edges of the plaits reddish. Male infl. gemmiform, bracts cucullato-incurved at apex.

HAB.—Trunks and roots of trees on river banks. Fr. 5—6.

Banks of the Ouse, near York, and of the Wharfe, and by the Cock, Tadcaster (*Spruce* 1842) !! Scotland by the Clyde (*Drummond* 1824). By the Thames, Wandsworth (*Sowerby*). Stapleton, near Bristol (*Thwaites* 1843) !! Henfield, Sussex (*Mitten* 1844) ! Near Temple Mill, Twycross (*Bloxam* 1844) !! By the Girvan, Dailly (*Dr. Wood*). Ilkley (*Carrington*). Kilvington and Mickley, Yorks. (*Baker* 1852) ! Thirsk (*Davies*). Dalam Tower park (*Berkeley* 1869). Castle Howard (*Slater*) !! Drumbridge, Down (*J. H. Davies* 1878). Birnam (*Carrington* 1857). Ross Bay (*Carrington* 1861).

A very distinct species and scarcely found out of the kingdom. It may be readily known by its distant soft leaves with large cells and dingy lurid colour; unfortunately it is commonly impregnated with mud, and does not make elegant herbarium specimens. Few of the North Yorkshire streams are without this and the preceding species.

13. *ORTHOTRICHUM STRAMINEUM* Hornsch.

Autoicous; in small loose tufts. Leaves lanceolate, carinate, acuminate. Caps. oblong-pyriform, emergent, with 8 broad striæ, vaginula hairy; cilia 8 or 16; calyptra campanulate yellow, slightly hairy. (T. LVII, D.)

Orthotrichum umbonatum BRID. Bry. univ. i, 787.

Dorcadion stramineum LINDB. Musc. scand. 28 (1879).

Autoicous; in small loose yellowish-green tufts, $\frac{1}{2}$ — $\frac{3}{4}$ in. high. Leaves imbricated when dry, or slightly flexuose, spreading when moist, long, lanceolate, acuminate, acute, or rounded obtuse and concave at point, or shortly apiculate, margin revolute, nerve disappearing at point in the upper leaves. Cells at base smooth, rectang., elongate next the nerve, passing gradually into rounded or subhexagonal, with thickened walls and prominent papillæ. Caps. more or less emergent, pachydermous, orange-brown, elliptic or oblong, suddenly narrowed towards base, with a short neck not defluent into pedicel, bands 8, more or less distinct, orange-brown, of 2—5 rows of quadrate cells with yellow thickened lateral walls, when dry the wrinkled capsule is more or less contracted below the mouth; stomata immersed, the border cells very prominent and nearly covering the stoma; annulus double, persistent. Teeth 8, bigeminate, yellow, reflexed when dry, sometimes perforated towards point or gaping in the median line, very finely papillose; cilia 8, subulate, of 1—2 rows of cells, wider at base, sometimes 8 intermediate cilia also present. Lid conic apiculate, yellow, pale red at margin. Calyptra covering most of caps., campanulate, apiculate, pale yellow with a brown point, slightly hairy. Vaginula very hairy. Male infl. at base of fertile branch.

Dorcadion Schimperi LINDB. Musc. scand. 28 (1879).

Autoicous; in small dense dark green cushions, stems very short, fastigiate. Leaves imbricated when dry, recurved from the base when wet, then patent, oblong-lanceolate, obtuse or acuminate at point, entire or erose and sometimes decoloured, nerve vanishing below point; cells at base quadrate at margin, elongate next the nerve, passing gradually upward to rounded or hexagonal, with thin walls and very small papillæ, margin revolute in lower half and then recurved to some distance below summit. Caps. small, immersed, rarely emergent, oval-oblong with a swollen neck, suddenly narrowed into a very short pedicel, bands 8, orange, of 4—5 series of quadrangular cells with thick lateral walls, descending to middle of capsule, when dry and empty, contracted and furrowed; stomata immersed, the border cells covering a large part of the stomatic cells; vaginula naked. Annulus persistent, of 2—3 rows of compressed cells. Teeth 8, bigeminate, small orange yellow, finely papillose, rarely perforated to the middle, when dry recurved to

the wall of capsule ; cilia 8, shorter than the teeth, and of the same colour ; lid conic, shortly apiculate. Calyptra naked or with a few short hairs, campanulate-hemispheric, plicate from base to apex, yellowish brown. Male infl. at base of female branch.

HAB.—On trees, rare. Fr. 4.

Kilcock, Meath (*R. Brown*). Copgrove, Yorks. (*Rev. J. Dalton*). Ripon (*Brunton*). On ash, Clifton Ings, York (*Spruce 1843*) !! Addingham, Bolton-br. (*Carrington 1858*). Malahide (*Moore 1871*). Rowardennan, Loch Lomond (*Dr. Wood 1875*).

I have not seen any British specimen of *O. pumilum* SWARTZ, and must therefore exclude it from our list ; it differs from *O. Schimperi* by the more cylindric capsule, with a distinct neck tapering gradually into the pedicel, and paler yellow ribs.

O. Schimperi is one of our smallest species, with the capsule immersed entirely or to the middle.

15. ORTHOTRICHUM PALLENS Bruch.

Autoicous ; in very small lax green tufts. Leaves lanceolate, concave and rounded at point. Caps. emergent, oval-oblong, tapering gradually downwards, with 8 broad striæ ; teeth 8 bigeminate, cilia 16, the alternate ones very small. Calyptra conic-campanulate, naked. (T. LVIII, A.)

SYN.—*Orthotrichum pallens* BRUCH in BRID. Bry. univ. i, 788 (1827). BR. SCH. Bry. eur. fasc. 2—3, p. 24, t. 13 (1837). RABENH. Deutsch. kr. fl. ii, S. 3, 184 (1848). C. MUELL. Synops. i, 701 (1849). Amer. 175 (1884). VENTURI in HUSS. Muscol. gall. 188, t. 51 (1887).

Dorcadion pallens LINDB. Musc. scand. 28 (1879).

Autoicous ; in very small, lax, irregular, pale green or yellow-green tufts, $\frac{1}{3}$ in. high, but little branched. Leaves imbricated when dry or loosely incumbent and slightly flexuose, when moist erecto-patent, from an oval-oblong base, lanceolate, the point concave and rounded, entire or crenulate at margin by projecting cells, or acuminate, or suddenly apiculate, margin revolute below the point ; cells at base rectang. nearly diaphanous, gradually passing into rounded, angular or hexagonal, with slightly thickened yellowish walls ; papillæ prominent simple or forked ; nerve vanishing below point. Perich. bracts longer, narrowly ligulate, carinate, strongly nerved to apex. Caps. emergent, oval-oblong, pale yellow, defluent insensibly into a neck long as sporangium, on a very short pedicel, vaginula naked or with some paraphyses, bands 8, orange,

of 2—4 rows of cells with thickened yellow lateral walls; stomata immersed, the border cells not turgid. Teeth 8, bigeminate, pale yellow, perforated at top, rarely cleft in the median line, finely papillose, cilia 8, smooth or papillose, filiform, with intermediate cilia very small or rudimentary. Lid conic, apiculate. Calyptra pale yellow, plicate, conico-campanulate, naked. Male infl. gemmiform, numerous, on a special branch, bracts ovate.

HAB.—On trees in hedges, rare. Fr. 5—6.

Clifton Ings, York, on willow with *O. Sprucei* (*Spruce* 1842)! Mickley, Yorks. (*Baker*).
Addingham, between Bolton and Ilkley (*Carrington* 1855)! Miney and Trungle,
Cornwall (*Curnow*). Westaston, Wicklow. Near Galway and Cork (*Carroll*).

This little moss has probably been overlooked, and has an elegant symmetric capsule and lingulate upper leaves with rounded points, the cells large for the size of the plant and resembling those of *O. tenellum*; the intermediate cilia are sometimes abortive. It may be known from *O. Schimperi* by its narrower and longer capsule with defluent neck, and more conical calyptra.

16. ORTHOTRICHUM TENELLUM Bruch.

Autoicous; in small loose deep green tufts. Leaves erecto-patent, oblong-lanceolate. Capsule emersed, narrow cylindric, with 8 broad bands: teeth 8 bigeminate, cilia 8; calyptra conic-campanulate, slightly hairy. (T. LVIII, B.)

SYN.—*Orthotrichum tenellum* BRUCH in BRID. Bry. univ. i, 786 (1827). WALLR. Fl. cr. germ. i, 209 (1831). HUEBEN. Musc. germ. 360 (1833). BR. SCH. Bry. eur. fasc. 2—3, p. 15, t. 6 (1837). DE NOT. Dorcadion tenellum LINDB. Musc. scand. 28 (1879).

Autoicous; in small loose deep green cushions $\frac{1}{3}$ — $\frac{1}{2}$ in. high. Leaves imbricated when dry, erecto-patent when moist, from an oblong base, lanceolate, the apex muticous, apiculate or acuminate, margin revolute nearly to point, nerve vanishing at apex; cells at base diaphanous, quadrate, elongate next the nerve, passing gradually into angular or rounded, with thickened walls and very faint papillæ. Caps. emersed for all the length of the sporangium, pachydermous, golden-brown, narrow cylindric, not contracted below the mouth, furrowed for all the length, when moist oval-cylindric, passing gradually into a short neck; bands 8, orange, broad and prominent, of 3—4 rows of quadrangular cells with strongly thickened lateral walls; stomata immersed, with strongly

projecting border cells. Annulus of 3—4 rows of compressed cells; teeth 8, bigeminate, pale brown, reflexed when dry, finely papillose, cilia 8, shorter than the teeth; vaginula smooth. Lid conic, apiculate, pale red at margin. Calyptra narrow, conic, greenish yellow, glossy, slightly hairy. Male infl. axillar.

HAB.—On Willows, Poplar, and Elder. Fr. 5—6.

Near Bantry (*Miss Hutchins*). Near York and at Matlock bridge (*Spruce* 1844)! Sussex (*Mitten*). Gresford and Nant-y-Belan, N. Wales (*Wilson* 1833)!! Thirsk and Ayton (*Baker* 1852). Bolton Abbey and Ilkley (*Gibson* 1834). Cartmel (*Carrington* 1859). By the Cherwell and near Heyford, Oxon. (*Boswell* 1859)! Derwentwater and Keswick (*Hunt* 1863)!! Mucross (*Carrington*). Orthotrichum stenocarpum BRID. Bry. univ. i, 271 (1826).

Dorcadion pulchellum LINDB. Musc. scand. 28 (1879).

Autoicous; in low loose soft olivaceous tufts. Leaves flexuose when dry, recurving slightly when moist, and then becoming erecto-patent, from an oval or oblong base, linear, acuminate, acute, the perich. bracts smaller and concealed by the upper leaves; margin loosely revolute in lower half, recurved above; nerve feeble, reaching to the point in the upper leaves; cells at base quadrang. elongated, gradually passing up into very minute rounded or subhexagonal, with thickened walls. Capsule small, yellowish, wholly exserted, oval-oblong, defluent on the pedicel, which passes but little the upper leaves, furrowed when dry and narrowed in the middle; bands 8, of 3—4 rows of quadrate cells

with slightly thickened lateral walls; stomata immersed, the border cells projecting or in some cases not. Annulus persistent, double, very narrow. Teeth 8, bigeminate, cleft nearly to base into 16, reflexed against wall of capsule, orange-red, very finely papillose, cilia 8, orange, usually with 8 intermediate ones. Lid conic, rostrate, yellow, red at margin. Calyptra conic, campanulate, naked, plicate, lacerate at base, yellowish with a fuscous point. Male infl. gemmiform, at base of a female branch.

HAB.—Trunks of trees, sometimes on walls. Fr. 5—6.

Frequent in subalpine districts. Hell-cleft and High Force, Teesdale (*Spruce* 1843)!! Paper Mill wood, Over (*Wilson* 1827)! Llanffinan (*Wilson* 1855)! Blair Athole (*Miss McInroy* 1859)! Var. β . *Winteri* (*Schimpf.*)

Tufts irregular, deep green above, fuscous at base, capsule more exserted, oblongo-cylindraceous, with paler peristome.

SYN.—*Orthotrichum Winteri* SCHIMP. Bry. eur. Suppl. III—IV, t. 11. Synops. 2 ed. 335. MILDE Bry. siles. 179. VENT. in HUSN. Musc. gall. 192, t. 52.

HAB.—Penzance, Cornwall (*Curnow* 1868)!! distributed in Rabenhorst's Bryotheca No. 1079, under the name of *O. pulchellum*.

This lovely little moss has the leaves slightly crisped when dry, and thus leads us towards the next genus, to which it also approximates by the lengthened fruit stalks; the red peristome, 16 cilia and smooth calyptra readily distinguish it. In the moorland districts of N. Yorkshire and the Lowlands of Scotland it is quite common.

8. WEISSIA EHRH.

Hannov. mag. 1779, p. 1003.

Growing in small cushions on trees or very seldom on rocks, the stems branched, erect or decumbent. Leaves long, lanceolate flexuose, curled and twisted when dry, the base dilated and concave, with linear chlorophyllose cells in the middle and dilated hyaline ones at the sides. Calyptra yellow, plicate, cleft at base, covered with long flexuose yellow hairs. Capsule oval 8-striate, exserted on a tall pedicel, with a very long neck, the peristome as in *Orthotrichum*, ochrea indistinct or none.—Der. after F. G. Weiss of Göttingen.

A very natural genus in habit and facies, and depending more on these for separation from *Orthotrichum*, than on any structural peculiarities,

although the calyptre and texture of the leaf-base are more or less distinctive. About 36 species are referable to it, some of which have creeping stems as in the genus *Macromitrium*. In all our species the stomata are superficial.

The acute botanist Ehrhart was certainly the first to found a genus in honour of Weiss, the subsequent one of Hedwig applied to *Bryum viridulum* (Fund. II, 90), dating from 1782; *Orthotrichum* is posterior to both, and if the two are to be united in one genus, it must stand as *Weissia*. The name Weis on the title of the "Pl. crypt. Gotting." is no doubt a printer's error, as the correct spelling must be Weiss.

CLAVIS TO THE SPECIES.

Leaves rigid, not crisped.	<i>Americana</i> .
— crisped when dry.	
Upper leaves tipped with a cluster of gemmæ.	<i>phyllantha</i> .
— not tipped with gemmæ.	
Caps. striate only at the contracted orifice.	<i>coarctata</i> .
— all its length.	
Stem creeping, leaves slightly curled, per. simple.	<i>Drummondii</i> .
— not creeping, l. strongly curled, per. double.	
Orifice of capsule contracted.	<i>Bruchii</i> .
— not contracted.	
Calyptre hairy; caps. contracted below orifice.	<i>ulophylla</i> .
Calyptre nearly smooth, caps. not contracted below orifice.	<i>vittata</i> .

I. WEISSIA AMERICANA (*P. Beauv.*) Lindb.

Autoicous; in rigid, fragile, brown tufts. Leaves erect, nearly straight when dry, lanceolate. Capsule clavato-pyriform, 8-striate; calyptre campanulate, hairy. (T. LVIII, D.)

SYN.—*Orthotrichum americanum* P. BEAUV. Prodr. 80 (1805). SCHWAEGR. Suppl. I, P. II, 37, et Suppl. II, P. I, 144, t. 138 (1823). BRID. Bry. univ. 278 (1826).

Ulotrichum Ludwigii SCHIMP. Consp. Bry. eur.

Weissia coarctata LINDB. Musc. scand. 28 (1879).

Autoicous; in small yellow-brown tufts, stems erect, decumbent at base, sparingly branched, fastigiate. Leaves densely imbricated, appressed and slightly crisped when dry, erect when moist, lanceolate acuminate, or from a narrowly ovate ventricose base, elongato-lanc., plane or recurved at margin, carinate, nerve vanishing below apex; cells at basal margin quadrate, hyaline, the rest very narrow, upper rounded and oval, incrassate. Capsule oboval, afterwards clavato-pyriform, pale fuscous, leptodermous, much contracted at mouth and with 8 short plaits below it, the rest scarcely sulcate, bands 8, short, of quadrate cells strongly incrassate laterally, those of the sulci rectangular; stomata numerous on the neck. Lid hemispherical, rostellate. Calyptra straw-coloured, densely hairy. Teeth 8, bigeminate, whitish, erect when dry, cilia 8, very short, or altogether obsolete.

HAB.—Young trees in subalpine woods. Fr. 8—9.

Hill of Finhaven (*Drummond*). Trossachs (*Wilson* 1832). Glen Falloch and Killin (*Hunt* 1865)!! Rowardennan (*Dr. Wood* 1875). Torc wood and Glena, Killarney (*Carrington* 1861). Danny, Sussex (*Mitten*). Clova (*Fergusson*).

Readily known by the very contracted mouth of the capsule, which gives it a very peculiar appearance, also by the short bands and plaits below it.

3. WEISSIA DRUMMONDII (*Hook. Grev.*) *Lindb.*

Autoicous; stem creeping, with erect branches. Leaves spreading, linear-lanc., appressed, and scarcely crisped when dry, nearly plane at margin. Caps. oblongo-pyriform, on a long pedicel; calyptora conico-campanulate, hairy, teeth 16, geminate, pale. (T. LIX, A.)

SYN.—*Orthotrichum Drummondii* HOOK. GREV. Edin. Journ. Sc. i, 120 (1824). GREV. Scott. cr. fl. t. 115 (1824). HOOK. TAYL. Musc. brit. 2 ed. 126, Suppl. t. 4 (1827). HUEBEN. Musc. germ. 345 (1833). Macromitrium Drummondii HAMPE in Flora 1837, p. 280.

Weissia Drummondii LINDB. Musc. scand. 28 (1879).

Autoicous; in depressed pale yellowish-green tufts, stems longly trailing, with erect branches and fasciculate shoots. Leaves erecto-patent when moist, erect straight and scarcely crisped when dry, lineal-lanceolate, obtuse, ovate and concave at base, plane or slightly recurved at margin, nerve vanishing below apex; basal cells linear in the middle,

quadrato-rectang. at margin, upper quadrato-rotundate, papillose. Capsule obovate-clavate, contracted at mouth, pale brown, obliquely 8-striate to base, fusiform when old, cells of striæ rectangular, leptodermous; lid pale with a subulate beak; teeth 16, geminate, whitish, recurving when dry; rudimentary cilia sometimes present. Calyptora very sparingly hairy.

HAB.—Trunks of alder, birch and mountain ash in subalpine districts.
Fr. 7—8.

Frequent in Forfar and Perthshire, Braemar, Loch Maree (*Hunt* 1866)!! High Force, Teesdale (*Spruce* 1842). Cronkley Fell (*Stubler* 1866)!! Powerscourt, Killarney and Luggielaw (*Moore*). Alford, Aberdeen (*Mrs. Farquharson* (1881))!!

This pretty species, by its creeping stems, resembles in habit the great exotic genus *Macromitrium*; the leaves are very slightly curled, and the endostome is wanting.

4. WEISSIA BRUCHII (*Hornschr.*) Lindb.

Autoicous; pulvinate, branched. Leaves linear-lanceolate, crisped when dry. Capsule on a long pedicel, oblong-pyriform, with 8 broad striæ, contracted at mouth when dry; calyptora very hairy. (T. LIX, B.)

SYN.—*Ulota Bruchii* HORNSCH. M^{es}. BRID. Bry. un. i, 794 (1827). SCHIMP. Synops. 256 (1860), 2 ed. 303. BERK. Handb. br. m. 229 (1863). MILDE Bry. siles. 167 (1869). JURATZ. Ulotrichum coarctatum SCHIMP. Conspl. Bry. eur.

Weissia Bruchii LINDB. Musc. scand. 28 (1879).

Autoicous; in soft pulvinate tufts, bright yellow-green above, ferruginous at base, the stems erect or ascending from a decumbent naked base, repeatedly dichotomous. Leaves from an ovate concave base, long, linear-lanceolate, subflexuose, twisted and contorted when dry, more gradually pointed than in *W. ulophylla* and with a paler nerve, margin plane above, recurved below; cells at basal wings quadrate, hyaline, with incrassate transverse walls, those next the nerve larger, rectangular, in straight rows, the upper with smaller papillæ; perich. bracts longer, erect, sulcate at base. Calyptora densely hairy. Capsule

on a long pedicel, oval-pyriform, yellow-brown, pachydermous, gradually attenuated into a long neck, 8-costate, when dry and empty elongated, fusiform, contracted at mouth, fuscous; cells of the bands in 5 rows, quadrate, thickened in the longitudinal walls; lid pale, convex, rostellate; teeth bigeminate, finally 16 and geminate, reflexed when dry, pale papillose, cilia 8, long as teeth, or 16 alternately long and short, narrow. Spores green, larger than in *W. ulophylla*.

HAB.—On trees; not uncommon. Fr. 7—8.

This is more robust than *W. ulophylla*, the leaves less crisped, with larger cells, those next the nerve at base longer and laxer; the capsule is more exserted, darker brown, when empty attenuated, fusiform, contracted and twisted at mouth. The two species sometimes grow together.

5. WEISSIA ULOPHYLLA Ekrh.

Autoicous; soft and pulvinate, branched. Leaves strongly crisped when dry, from a concave ovate base, linear-lanceolate. Caps. clavate, attenuated in a long neck, strongly striate, contracted below the wide mouth; calyptra very hairy. (T. LIX, D.)

Autoicous; in dense rounded cushions, or rather lax and irregular in outline, yellow green above, ferruginous at base, bearing old and young capsules at the same time. Stems erect or decumbent at base, branched; leaves densely crowded, strongly curled and twisted when dry, patulous when moist, from a concave ovate base, linear-lanceolate, the margin recurved in the lower half, nerve yellow, reaching nearly to apex; cells at base rectangular, brown, the alar hyaline with thickened transverse walls, those towards the nerve elongated, in oblique rows, upper rounded, incrassate. Capsule exserted, leptodermous, oval, gradually attenuated, in a long neck and strong scarcely twisting pedicel, 8-striate, contracted below the wide orifice, younger ferruginous the old brown or straw-coloured, after maturity and when dry, elongate fusiform, deeply sulcate; cells of the vittæ in four rows, rufous; lid hemispherical, long-pointed; teeth 8, bigeminate, pale, cilia 8, or rarely 16, narrowly lanceolate, of two rows of cells up to middle. Calyptra pale yellow, very rough, campanulate. Male infl. lateral.

HAB.—On trees; common in subalpine districts. Fr. 5—6.

Var. β . *intermedia* Schimp.

Leaves longer, with more numerous quadrate hyaline cells at basal margin; caps. more cylindric, not contracted below the mouth, less tapering at base.

SYN.—*Ulota crispula* β . *ambigua* SCHIMP. Synops. 258.

Ulota intermedia SCHIMP. Synops. 2 ed. 305. JURATZ. Laubm. oest.-ung, 196. HUSN. Musc. gall. 152, t. 43.

HAB.—Here and there with the typical form.

Near Loch Lomond (Schimper 1868)! Castle Howard (Spruce 1847)! Dunoon (Shaw 1860)!! Wychwood forest, Stokenchurch and Bagley wood (Boswell). Rosslyn and Skye (Boswell). Strome ferry (Dixon 1883).

Var. γ . *crispula* (Bruch) Hammar.

In smaller tufts. Leaves narrow and shorter, more laxly areolate. Caps. pale, leptodermous, oval-pyriform, with a long neck, when dry and empty, short truncate urceolate, scarcely contracted below the mouth, the neck suddenly contracted and plicate.

SYN.—*Orthotrichum crispum* β . *minus* SCHWAEG. Suppl. I, P. II, 25.

Ulota crispa β. *crispula* HAMMAR Mon. 24.
Weissia crispula LINDB. Act. soc. sc. fenn. x., 12.

HAB.—Subalpine districts.

Not unfrequent in the Lake country, N. Yorkshire and S. Scotland.

Weissia ulophylla in its typical form is best known by the old capsule having a wide trumpet-shaped mouth, and being contracted below it, the var. *intermedia* however has the capsule scarcely showing any constriction, and yet we occasionally meet with some where this is decidedly evident, so that we cannot look upon it as other than a mere form. We must also agree with Dr. Carrington in regarding *W. crispula* as nothing more than a variety, for although at first sight the small thin pale abbreviated capsule, suddenly contracted at base into a tapering neck, appears to be characteristic, numerous transition forms occur so linked with the typical, that it is not possible to maintain them as distinct. I have to thank Mr. Holt for a long series of specimens from various localities which have confirmed me in this view of the species.

6. WEISSIA VITTATA (Mitt.) Braithw.

Autoicous; circrato-crispate when dry. Leaves lineal-lanceolate. Calyptra glossy straw-colour, almost naked. Caps. oval-oblong, with a long neck, not contracted below mouth. (T. LIX, C.)

SYN.—*Ulota vittata* MITT. Journ. Linn. soc. viii, 3 (1864).

Weissia vittata BRAITHW. in Journ. Bot. 1873, p. 202.

Orthotrichum Paivanum SCHIMP. MSS.

Autoicous; in small yellow green cushions. Leaves densely crowded, patent, circrato-crispate when dry, from an oval base, which has a deep furrow on each side, lineal-lanceolate, basal cells sub-vermicular, quadrate at margin, and with 5—8 rows of very narrow rectangular cells next the margin, forming a band as high as the middle of leaf, apical irregularly rounded-hexagonal, very small, narrower than in *W. Bruchii*. Perich. bracts rather shorter than comal leaves; vaginula naked. Calyptra glossy straw-colour, with very few hairs. Caps. on a longer more slender subflexuose pedicel, oval-oblong, with a very long neck gradually attenuated into pedicel, but little altered when dry and empty, less deeply sulcate, not contracted at or below mouth; teeth larger, bigeminate, partly separated at apex, or perforated between when

dry, spreading and reflexed against wall of capsule, very densely papillose externally, cilia 8, filiform, long as teeth, pale yellowish. Male infl. terminal.

HAB.—Branches of small trees; not common. Fr. 6.

On hawthorn and Mountain Ash at Torc waterfall, Killarney (*Moore* 1858)!! Loch Finnehy, Kerry (*Spruce* 1842)! Muckross and O'Sullivan's Cascade. Glenshesk, Antrim (*Stewart* 1882)!! Glenariffe, Antrim (*Stewart* 1889)!! Rowdennan, Loch Lomond (*J. Bury* 1859). Westmoreland (*Barnes* and *Stabler*).

With the habit of *W. Bruchii*, this fine species is quite distinct, the calyptra being nearly bare, and the marginal band of long narrow cells a marked feature, these cells vary in number and extent in different leaves, but are always more or less evident; Mr. Stewart's specimen bears scattered oblong gemmæ on the leaves. The species was first discovered by Mr. Johnson in Madeira.

7. WEISSIA PHYLLANTHA (*Brid.*) *Lindb.*

Dioicous; densely pulvinate. Leaves long, lineal-lanceolate, not dilated at base, strongly crisped when dry, the upper with the nerve thickened at apex and bearing a cluster of septate gemmæ. Caps. oval-oblong, not contracted at mouth. (T. LIX, E.)

SYN.—*Ulota phyllantha* BRID. MANT. 113 (1819). HAMMAR Mon. Orth. suec. 30 (1852). SCHIMP. Coroll. Bry. eur. 41 (1855), Synops. 259 (1860), 2 ed. 306. BERK. Handb. Br. m. 230 (1863). Gymnostomum viridissimum DAVIES Welsh Botan. 103 (1813).

Ulotrichum phyllanthum SCHIMP. Bry. eur. Conspec.

Weissia phyllantha LIND. Musc. scand. 28 (1879).

Dioicous; densely pulvinate, bright yellow-green above, ferruginous below; stems $\frac{1}{2}$ —1 in. high, erect, but little branched. Leaves circinato-crispate and twisting when dry, long, lineal-lanceolate, not dilated at base, obtuse, very slightly concave, revolute at margin below, nerve stout, vanishing at apex, in the upper leaves expanded into a thick point bearing a cluster of fuscous elliptic septate propagula; cells above minute, quadrate, papillose, at the plicate base pale, rectangular, the lowest rufescent, with only a single series of hyaline ones at margin. Perich. bracts much elongated, sinuoso-crenulate at margin; vaginula naked, caps. on a longish yellow seta, oval-oblong, not contracted at mouth, plicate when dry, with a longly attenuated neck, pale green

when young, fuscous when old, and with 8 strong twisted ridges; teeth 8, bigeminate, pale, truncate and slightly lacerate at point, not reflexed when dry, cilia 8, broad and short, of two rows of cells. Calyptra slightly hairy. Lid conic-acuminate, pale yellow, with a reddish margin. Spores green, very finely punctulate. Male infl. gemmiform, among the comal leaves; bracts oblong, acuminate, mucronate with the excurrent nerve.

HAB.—Trees and rocks near the sea; not uncommon; also found inland. Fr. 5.

High rocks, Tunbridge wells, with 1 caps. (Spruce 1846)! Mucross, Killarney, 5 caps. (Schimper 1868)!

In appearance this somewhat resembles *W. crispa* but has longer leaves, not dilated at base, the quadrate hyaline cells only forming a single row at margin, and the upper leaves generally tipped with a cluster of brownish gemmæ. The fruit was first described by MM. Renauld and Cardot, from specimens collected in Oregon, by Mr. T. Howell, and a sharp-eyed American lady (Mrs. Britton, of Columbia College), when working at Kew last autumn, found 5 capsules on the specimen collected by Schimper himself at Killarney, but which had not been noticed. This led our veteran bryologist, Spruce, to look over his early gatherings, and among some *W. crispa*, collected by him at Tunbridge Wells, the same lady detected a single damaged capsule of *W. phyllantha*.

The inland specimens from Yorkshire, Sussex, &c., are shorter and paler than those from the coast, and I have noticed it particularly fine and abundant at Lochinver, Sutherlandshire.

SCHISTOSTEGA MOHR.

Schistostega osmundacea (*Dicks.*) *Mohr.*

Fam. II. SCHISTOSTEGACEÆ.

Plants very small and slender, of two forms, with persistent branching confervoid protonema, simple, rooting only at base; fertile stems naked below, frondiform, with the leaves bifarious, inserted vertically and confluent at base, or only with a terminal rosette of smaller leaves, inserted horizontally and quinquefalous, sterile stems larger, frondiform. Leaves all nerveless, plane, oval-rhomboid, with lax prosenchymatous rhomboidal cells. Capsule minute, globose-oval, exannulate, gymnostomous. Calyptra cylindrico-conical, minute, fugacious. Lid convex. Inhabits dark holes and caverns.

SCHISTOSTEGA Mohr.

Obs. botan. 26 (1803).

Plants small, slender, naked below. Leaves dimorphous, bifarious and inserted vertically or smaller and comant, inserted horizontally, lanceolate, nerveless, laxly areolate. Capsule minute, globose, gymnostomous; calyptra minute, conical, dimidiate. Der. $\sigma\chiιστος$ cleft, $\sigma\tauεγη$ a lid, applied in error.

SCHISTOSTEGA OSMUNDACEA (Dicks.) Mohr.

The only species of the genus. (T. LX.)

Fam. 12. SPLACHNACEÆ.

Plants gregarious or cæspitant, dichotomous with few branches. Leaves slender-nerved, broad, membranous and flaccid, the cells large lax pellucid, rhombic or pentagonal, smooth. Infl. terminal, the male subdiscoid or capituliform. Capsule on a tall seta, subcylindric, erect, with a distinct hypophysis which is obconic, pyriform, globose or umbrella-shaped, collapsing when old; calyptra cucullate and cleft on one side or conic and entire; peristome of 16 geminate or 8 bigeminate lineal-lanc. teeth, strongly hygroscopic; spores smooth. Inhabiting the earth, but especially on rotten dung and other animal matters.

This distinct family comprises about 40 species, some of them ranking amongst the most elegant of known mosses, and especially remarkable for the great spongy and often gaily coloured hypophysis, which forms the major portion of the fruit.

The cleistocarpous genus *Voitia* HORNSCH. finds its most natural place in this family.

I. SPLACHNUM L.

Sp. plant. 1108 (1753).

Plants laxly tufted, with slender dichotomous stems. Leaves remote, patulous, the upper rosulate, broadly obovate-lanc. narrow at base, cells very lax, hexagonal. Caps. on a long seta, oval and shortly cylindric, on a very much larger hypophysis of a different colour, and pyriform, globose or umbraculiform; teeth of peristome 16, lineal, geminate, reflexed when dry. Inhabiting rotten peat and dung.—Der. Σπλαγχνον used by Dioscorides for the lichen *Sticta pulmonaria*.

This genus comprises 7 species which fall naturally into two sections according to the form of the hypophysis; in the first of these, *Ampullaria* C. MUELL.—to which all our British species belong,—this organ has the form of an inverted flask, but in *Umbracularia* it is immensely dilated like an expanded umbrella. The species referable to the latter are *S. rubrum*, *luteum* and *melanocaulon*, and it is quite possible that *S. luteum* may turn up in some of the deer forests of Sutherland or Caithness, although all three are most at home in Lapland.

CLAVIS TO THE SPECIES.

Hypophysis vesicular, tapering downward.	
—globose.	<i>ampullaceum.</i>
Leaves very obtuse, entire.	
—longly acuminate, acute.	<i>vasculosum.</i> <i>pedunculatum.</i>

I. SPLACHNUM AMPULLACEUM L.

Autoicous and dioicous; leaves obovato-lanc. acutely acuminate, serrate in upper part; caps. oblong with a large inversely flask-shaped hypophysis tapering down into the seta. (T. LXI, A.)

Splachnum Turnonianum DICKS. Cr. fasc. 2, p. 3, t. 10, f. 11 (1790). BRID. Sp. musc. I, 153; Mant. 108. SM. Eng. Bot. t. 1116; Fl. brit. 1176.

Autoicous and dioicous, in small lax tufts. Lower leaves lanceolate, upper obovato-and elongato-lanc. with a long acute point, coarsely serrate at point, very soft, pale green, the nerve vanishing below apex. Caps. ovali-cylindric pale yellow, the hypophysis large, pyriform, succulent, pink when young, purple when old, defluent on a long purple seta; lid convex, yellow, teeth pale yellow, rather obtuse, 8 bigeminate and erect, finally 16 geminate and reflexed against caps. wall. Male infl. terminal, the bracts broadly oval at base, longly lineal-subulate.

HAB.—On dung on wet heaths. Fr. 5—6.

Near Itchin Ferry (Sherard). Near Addington, Surrey (Dillenius). Snowdon (Griffith). Exeter (Turner). Ashdown Forest (Borrer). Terrington Carr, Yorks. (Teesdale)!! Ross, Hereford (Watkins)!! S. vasculosum Var. *acutifolia* GREV. Scott. cr. fl. t. 311.

Dioicous; in soft swelling deep green tufts, black at base. Stems nearly simple or innovating, radiculose, 1—3 in. high. Leaves large, distant, narrow at base, lower suborbiculate, upper broadly ovate, somewhat acuminate, obtuse, entire, nerve thin vanishing below apex; cells oblong-hexagonal. Caps. shortly cylindric, rufous, seta pale red, long as stem, hypophysis large spherical, minutely tubercular, dark purple-brown, wrinkled when dry and becoming black by age; lid convex, yellow; teeth conjoined in pairs, shorter, orange. Male plants more slender, often in separate tufts, the leaves smaller and more remote, infl. terminal, the bracts from a broadly oval sheathing base, longly acuminate, obtuse.

HAB.—Wet peaty places in the Highlands. Fr. 7.

Ben Lawers (*Mackay* 1803)!! Clova (*Don*). Ben More of Dochart. Fewla burn and Loch Brandy (*Gardiner*)!! Glass Mhiel (*J. B. Syme* 1851). Glen Prosen (*Fergusson* 1868)!!

A fine moss only found at considerable elevations and in boggy places, the old capsule becoming singularly wrinkled and pitted.

3. **SPLACHNUM PEDUNCULATUM (Huds.)**

Dioicous; laxly tufted. Leaves spreading, obovate-acuminate, entire or serrated, nerved to apex. Capsule subcylindric, hypophysis ovate or subspherical, teeth large, lineal, reflexed. (T. LXI, C.)

HAB.—In similar localities, but more common.

This moss varies very much in size, and in the width and serration of the leaves, and sometimes the filiform seta attains a length of 7 inches. The difference between the typical form and the variety lies in the hypophysis, which is more elongated in the former. Dickson's *S. ovatum* is represented on fig. 2A.

2. TETRAPLODON Br. Sch.

Bry. eur. fasc. 23—24 (1844).

Densely cæspitoso-pulvinate, interwoven below with radicular tomentum. Leaves elongate-lanc. or ovate-oblong, running out into a subulate point. Calyptra conico-cucullate, then cleft to middle; caps. oval-cylindric, solid, with a thicker obconic solid hypophysis of same colour; teeth shorter, conjoined in fours, solid, finally geminate, reflexed when dry, columella not exserted. Der. $\tau\epsilon\tau\rho\pi\lambda\omega\varsigma$ fourfold, $\omega\delta\omega\varsigma$ a tooth.

This small genus of 4 species differs from *Splachnum* principally in the fruit, the capsule and hypophysis being of the same colour and consistence, and the latter not inflated.

CLAVIS TO THE SPECIES.

Seta elongated; leaves entire.
— very short; leaves serrated.

bryoides.
angustatus.

1. TETRAPLODON BRYOIDES (*Zoega*) Lindb.

Autoicous; leaves obvate, suddenly attenuated into a long point, entire. Caps. on a long seta, oval, blackish, with an obovate hypophysis; lid conic, obtuse. (T. LXII, A.)

Autoicous ; in irregular lax tufts, soft, slender, with rufous tomentum. Leaves broadly spathulate, shortly acuminate, very thin and flaccid, pale with lax irregular hexagonal cells, margin serrated above, nerve reaching nearly to apex. Caps. on a slender seta, small oval, with a long narrow tapering hypophysis, pale brownish becoming black by age, when dry and empty strongly contracted below, with a wide mouth ; columella much exserted ; teeth long, dark purple, glossy, reflexed when dry and closely appressed to the capsule : spores larger. Male infl. terminal on special branches or at the base of innovations, capituliform.

HAB.—Rotten turf on mountains ; rare. Fr. 7—8.

Leney (*Dr. Buchanan* 1782). Ben Lawers (*Dickson*). Head of Glen Callater (*G. Don*) ! Killin (*Binstead* 1885) !! Benbradagh Mtn., Co. Derry, Ireland (*Stewart* 1868) !!

Very distinct in the ripe stage, by its narrow contracted hypophysis and wide mouthed capsule with long exserted columella. It evidently differs

from *T. serrata*, and had been confounded with it from the circumstance of growing intermixed.

Sect. 2. CYRTODON (*Brown*). Peristome not reflexed when dry; columella slightly or not exserted. Leaves obtuse, entire. Male infl. gemmiform.

2. **TAYLORIA LINGULATA** (*Dicks.*) *Lindb.*

Synoicous; tall, densely tufted. Leaves erecto-patent, lingulate, obtuse, entire, nerve ceasing below apex. Caps. obovate, with a short neck tapering into seta; teeth of peristome 16, equidistant, yellow. (T. LXII, D.).

Fam. 14. FUNARIACEÆ.

Plants terrestrial, soft, gregarious or laxly tufted. Leaves ovato-lanceolate, with a thin nerve, cells large, lax hyaline smooth, hexagonal or oblongo-rhomboid. Caps. spherical, oval or pyriform, with a distinct neck, erect or cernuous, regular or gibbous, peristome none, single or double, teeth 16, acuminate and twisted to the right, or small and straight, calyptra inflated, with a long beak, cleft on one side or many-lobed.

This family, numbering about 135 species, is principally characterised by its large lax parenchymatous cells, and pyriform capsules, inflated calyptra and oblique cartilaginous teeth. The majority are found in the temperate regions of the northern hemisphere, but many occur in S. America and Australia.

Subf. 1. Discelieæ. Plants nearly stemless, gemmiform, attached to persistent protonema; leaves sheathing nerveless, with lax hexagonal cells, without chlorophyl. Caps. on a long seta, subglobose, inclined; peristome of 16 lanceolate teeth, cleft and gaping in the lower half.

I. DISCELIUM. *Brid.*

Bry. univ. i, 365 (1826).

Calyptra very narrow, cleft on one side with the margins involute at base. Caps. subglobose with a short neck, teeth 16, cartilaginous, lanceolate, cleft in the middle, trabeculate.—Der. δις two, σκελος a leg.

MILDE Bry. siles. 188 (1869). LESQ. JAMES Moss. N. Amer. 188 (1884).

Dioicous; plants annual, nearly stemless, attached to green protonema. Leaves few, imbricated sheathing, ovato-lanceolate, entire, with only faint traces of a nerve, cells large lax hyaline, oblongo-hexagonal. Caps. very small, on a long flexuose red seta, pachydermous, reddish-brown, subglobose, cernuous on a suddenly bent neck; calyptra narrow, subulate, fugacious, split up on one side, contracted at base and often left behind adhering to the seta; annulus large, subsistent, of two rows of cells, lid convex-conic; teeth 16, red lanceolate striate, cloven half way from the base upward. Male plants minute, gemmiform, nestling on the protonema, antheridia few, with subclavate paraphyses.

HAB.—Clay banks, rare. Fr. 2—3.

About Manchester (*Caley*)!! By the Tay near Perth (*Don*). Shibden and Todmorden, Yorks. (*Nowell*). Marple, Cheshire (*Whitehead*). Boggart hole Clough, and Haughton Dale, Lancashire. Ram's Clough, Ashton-under-Lyne. Berrow bridge, Bolton (*J. Sims* 1888)!! Kirby Bank, Cleveland (*Rev. J. Dalton, Jun.*)

This curious moss is clearly most allied to *Funaria* by the cell structure of the leaves, although the form of the capsule at once reminds us of *Catoscopium*, yet the broad annulus is also Funarioid, while the teeth of peristome are rather *sui generis*, though resembling those of *Trematodon*. The green protonema covers the clay banks where it grows, in autumn, and this turns red and withers away after the fruit is formed, and in spring the whole surface generally crumbles away and disappears until the following autumn.

Subf. 2. Amblyodontæ. Stem elongated, branched. Capsule asymmetric, pyriform; peristome double, outer of 16 short erect obtuse teeth, inner much longer of 16 lanceolate fissile teeth on a short membrane. Calyptra narrow, cucullate.

AMBLYODON P. Beauv.

Prodri. 41 (1805).

Calyptra very fugacious, cucullate, narrow. Caps. pyriform, asymmetric; peristome of 16 short lanceolate obtuse erect teeth, endostome a short sulcate membrane with 16 lanceolate subulate teeth much longer and splitting in the middle. Leaves Funarioid in structure. Der. $\alpha\mu\beta\lambda\nu\sigma$ obtuse, $\delta\delta\sigma\sigma$ a tooth.

Nanomitrium tenerum LINDB. in Not. ur Sällsk. 1. c.

Synoicous; plants very minute, nidulant in persistent protonema. Leaves broadly ovato-lanceolate, nerveless, obtusely serrate in the upper half, cells lax rhomboid-rectangular. Caps. nearly sessile, leptodermous, globose, immersed, apiculate or muticous, soft and pale; calyptra very short and small, closely adhering to apex of capsule; vaginula large, truncate, obovate; spores slightly verrucose, not large.

HAB.—On mud removed from a fish-pond at Pond Leigh, Hurstpierpoint (Mitten 1854)! ! Fr. II.

This remarkable little moss was first found by Breutel, at Niesky, and once only, and Mr. Mitten informs me that he also found it in abundance in the locality mentioned, but he has never met with it since. As a genus it differs from *Ephemerum* by the flattish cap-like calyptra, and the lax smooth non-incrassate leaf-cells. The name *Micromitrium* being already adopted by Spruce for a group of Orthotrichæ, Lindberg changed Austin's generic name to the equally appropriate one of *Nanomitrium*. Three more species are found in America.

-4. PHYSCOMITRELLA Br. Sch.

Bry. eur. Fasc. 42 (1849).

Plants minute, without protonema. Leaves rosulate, thin nerved, with lax 5—6 angled cells. Caps. on a short pedicel, cleistocarpous, immersed or exserted, globose, minutely apiculate; calytra conico-campanulate. Der.—diminutive of *Physcomitrium*.

HAB.—Chapel-en-le-Frith, Derby. (Prof. BARKER, 1887)!

5. PHYSCOMITRIUM. *Brid.*

Bry. univ. i, 97 (1826).

Plants resembling *Funaria*. Calyptra small fugacious, mitræform, cleft, rostrate, covering only the upper half of capsule. Caps. symmetric, pyriform, lid from a slightly convex base, abruptly rostrate or apiculate; peristome none. Der. $\phi\psi\sigma\kappa\eta$ a bladder, and $\mu\pi\tau\rho\iota\omega$ a calyptra.

For this genus of some 30 species, Lindberg retains the old title *Gymnostomum* HEDW., but as that genus was simply a receptacle for all the mosses which had no peristome, I have preferred the later but more definite title, as its most distinctive character depends on the inflated lobulate calyptra.

I. PHYSCOMITRIUM SPHÆRICUM (*Ludw.*) *Brid.*

Autoicous; leaves obovate, concave spreading, obtuse entire, nerve ceasing below apex. Caps. on a short seta, semiglobose with a distinct neck; lid obtusely conical. (T. LXIV, E.)

SYN.—*Gymnostomum sphæricum* LUDW. MSS. SCHKUKR Deutsch. kr. gew. P. 2, 26, t. 11 b. (1810). SCHWAEG. in SCHRAD. Neu J. Bot. iv, 15, t. 2, f. B. (1810), et Suppl. I, P. I, p. 21, t. 8 (1811). (1860), 2 ed. 375. BERK. Handb. 174 (1863). MILDE Bry. siles. 192 (1869). LINDB. in Not. ur Saell. Fn. Fl. fenn. 1870, p. 54. HOBK. Syn. 128 (1873). HUSN. Mouss. nord.-ouest 114 (1873), Musc. gall. 212, t. 57 (1888). JURATZ. Laubm. oester.-ung. 237 (1882).

Autoicous; minute, densely gregarious. Leaves rather dense, suberect, subcymbiform-concave, obovate, obtuse, quite entire, nerve vanishing below apex, the upper cells small subquadrate. Seta short reddish, twisting to the right when dry, caps. semiglobose, smooth of small roundish cells, with 2—3 rows at orifice rectangular, not constricted

below the wide mouth, annulus simple, fragmentary; lid nearly flat, shortly and obtusely rostellate.

HAB.—Dried mud at Mere Mere, Cheshire (*Wilson*, 1834)!! Fr. 9—10.

This rare little moss resembles some of the *Phasca* in the unpleasant habit of disappearing for years, and then suddenly reappearing, as it did in 1868, when Mr. Hunt collected splendid specimens. A closely allied species *Physc. curystomum* (N.-ESEN.) SENDTN. has been found growing with this in Germany, Holland, and France, and differs in the apiculate obtusely serrate leaves, with larger polygonal upper cells and a taller and larger capsule.

2. PHYSCOMITRIUM PYRIFORME (L.) Brid.

Autoicous; leaves distant erecto-patent, obovato-lanceolate, coarsely serrate above, nerve vanishing below apex. Caps. on a long seta, shortly pyriform, lid convex-conic, shortly rostellate. (T. LXIV, F.)

Autoicous ; densely gregarious or matted, pale green, stem 3—6 lines, often divided ; leaves distant, erecto-patent, flaccid, obovate-oblong, abruptly acuminate, obtusely serrate in upper half, nerve vanishing in the point, cells large oblong-hexagonal. Calyptra erect, 4—5 lobed at base. Caps. on a long seta, erect, roundish-pyriform, contracted below the mouth when dry, rufo-fuscous, smooth, the marginal cells rectangular in 12—16 rows, the neck short and well-defined, annulus of two rows of cells, lid convex-conic, shortly rostellate, spores spinulose.

HAB.—Moist banks and borders of ditches ; not uncommon. Fr. 4.

Readily known by the lobed calyptra from the similar *Funaria fascicularis*, which has also a plano-convex lid.

6. FUNARIA Schreb.

In L. Gen. plant. 8 ed. ii, 760 (1791).

Plants short and simple, inhabiting the ground, with laxly areolate ovato-lanc. leaves. Calyptra long-persistent, covering the greater part of the fruit, large inflato-cucullate, entire at base, long-beaked. Caps. pyriform, oblique and cernuous, or symmetric and erect ; lid plano-convex, sometimes mamillate ; peristome double, simple or none, teeth 16 often twisted obliquely to the right, with their points attached to a central disc ; endostome of 16 lanc. processes opposite to the teeth and adhering to them at base. Male infl. discoid, on a short branch.—Der. from *funis* a rope, referring to the twisted seta.

The genus *Funaria* comprises nearly 100 species, the larger half belonging to the section *Entosthodon*, which is connected to *Funaria* by such a gradually ascending series of closely allied species, that they can only form one extremely natural genus, the distinctive characters of which reside in the form of the calyptra and operculum. The peristome attains its highest development in *F. hygrometrica*, in which the teeth are spirally twisted and at about $\frac{2}{3}$ their length dip straight downwards and then inwards to be attached to a little central sieve-like disc, affording a beautiful object for the microscope.

CLAVIS TO THE SPECIES.

Capsule symmetric.	
Peristome none.	
Leaves bordered, caps. short-necked.	<i>obtusa.</i>
— not bordered, caps. long-necked.	<i>fascicularis.</i>
Peristome single.	<i>attenuata.</i>
Capsule asymmetric, gibbous.	
Caps. smooth, annulus none.	<i>calearea.</i>
— striate, ann. large, coloured.	
Lid very small, subconic, endostome rudimentary.	<i>microstoma.</i>
— broader, convex, endos. well developed.	<i>hygrometria.</i>

Sect. I. ENTOSTHODON. Capsule nearly regular, erect, peristome none, simple or sometimes double.

I. FUNARIA OBTUSA (*Dicks.*) *Lindb.*

Autoicous; laxly gregarious. Leaves oval-lanc., with a thickened border, obsoletely toothed. Caps. erect, sub-globose, short-necked, lid convex, peristome none. (T. LXV, A.)

Entost. Curnowii DAVIES MSS. a robust form.

Funaria obtusa LINDB. in Not. ur Saells. Fn. et Fl. fenn. foerh. xi, 65 (1870).

Autoicous; loosely gregarious, simple or branched, fulvescent, slightly glossy. Lower leaves remote, lanc., upper crowded in a coma, broadly obovato-lanc., acuminate, with a yellowish border of 1—3 rows of long very narrow cells, the margin obtusely dentate or nearly entire; nerve vanishing below or at the apex, yellow, fuscous when old; cells lax and pellucid. Caps. rather small, erect on a straight seta, sub-globose with a short neck, solid, rufescent, when dry and deoperculate slightly contracted below the mouth, gymnostomous; calyptre inflated, cucullate; lid convex, mamillate.

HAB.—Wet heaths and banks of sandy clay; common in subalpine districts.
Fr. 3—4.

A very variable plant as to size and also in the length and width of the leaves; it much resembles *F. fascicularis* from which it is immediately distinguished by the narrowly limbate leaves.

2. FUNARIA FASCICULARIS (Dicks.) Schimp.

Autoicous; densely gregarious. Leaves oblongo-lanc., acuminate, serrate, not limbate. Caps. erect, shortly pyriform, peristome fugacious; lid convex. (T. LXV, B.)

Autoicous; densely gregarious and subcæspitant, deep yellow-green. Lower leaves very small, the comal patulous, oblongo and spathulato-lanc., acuminate, sharply serrate in the upper part, not limbate, twisting somewhat when dry, nerve vanishing below apex. Caps. on a straight reddish seta, a little asymmetric, spherical, or with the short neck, shortly pyriform, reddish-brown, contracted and more elongated when old, not annulate; calyptra inflated yellowish, lid small, convex, the cells spirally oblique, peristome rudimentary and fugacious, consisting of short papillose fragments, spores strongly verruculose.

HAB.—In fields and on banks, generally distributed in subalpine districts, but not common. Fr. 4—5.

Most resembling *Physcomitrium pyriforme*, but readily distinguished by the different calyptra and lid.

3. FUNARIA ATTENUATA (*Dicks.*) *Lindb.*

Autoicous; densely gregarious. Leaves in a spreading rosette, broadly obovate-oblong, acuminate, the margin slightly crenate, nerve vanishing. Caps. erect, pyriform with a long defluent neck, teeth of peristome 16, small lanceolate-subulate, lid flattish convex. (T. LXIV, C.)

Funaria attenuata LINDB. Not. ur Saells. Fn. et Fl. fenn. foerh. xi, 64 (1870).

Autoicous; laxly or densely gregarious, simple. Cauline leaves very small, few and distant, comal in a patent rosette or laxly imbricated, broadly obovate or spatulate-oblong, acuminate, the margin slightly crenate by projecting cells, with a very narrow yellow border, nerve vanishing below apex. Caps. on an orange seta, erect pyriform with a long neck attenuated downward, leptodermous, yellowish-brown, finally truncate obconic and rufous-fuscous; annulus none, lid flattish convex; teeth of per. 16, from a confluent base, lanceolate-subulate, remotely articulate, pale and papillose, when dry depressed and connivent.

HAB.—Shady banks and wet sandstone rocks. Fr. 6—7.

Not uncommon in Ireland, West of Scotland and Wales. Lake district. Plymouth (*Holmes*) !! By Clifton Viaduct, Manchester (*Horsefield*).

Varies much in the length and width of the leaves and generally found on dripping banks of streams, intermixed with other mosses.

Sect. 2. EUFUNARIA. Capsule oblique, gibbous, cernuous, peristome present.

4. **FUNARIA CALCAREA** *Wahlenb.*

Autoicous; leaves obovate-oblong, suddenly apiculate, margin obtusely serrate, nerve vanishing. Caps. shortly pyriform, not annulate, smooth. (T. LXV, D.)

HAB.—Same localities as the type.

St. Vincent's rocks (*Thwaites* 1843). Worthing and Torquay (*Mrs. Robertson* 1859)! Plymouth (*Holmes* 1868).

The two species here brought together have both been referred to a third—*F. Muehlenbergii*—an American moss which appears to be distinct.

This has led to inextricable confusion in the synonymy, which Lindberg attempted to end by renaming them; his *F. Americana*=the genuine *F. Muehlenbergii* HEDW. f., his *F. Mediterranea*=*F. Muehlenbergii* TURN., and his *F. calcarea*=*F. hibernica* Hook.; that the last is perfectly correct is clear from Wahlenberg's beautiful figure, and also that it must stand as the type of the species, being a larger plant with larger and more sharply serrate leaves, but that these trivial differences are sufficient to maintain the other even as a variety must be answered in the negative, for every stage of projection of the marginal cells constituting the teeth, may be noticed down to an almost entire edge to the leaf.

5. FUNARIA MICROSTOMA Br. Sch.

Autoicous; resembling *F. hygrometrica*. Leaves oval, acuminate, entire, nerve lost in the point. Caps. decurved, annulate; lid small, subconic, endostome rudimentary. (T. LXV, E.)

Woolston moss (*Wilson*) !! Arniston woods, Edinburgh (*J. B. Syme* 1860) !

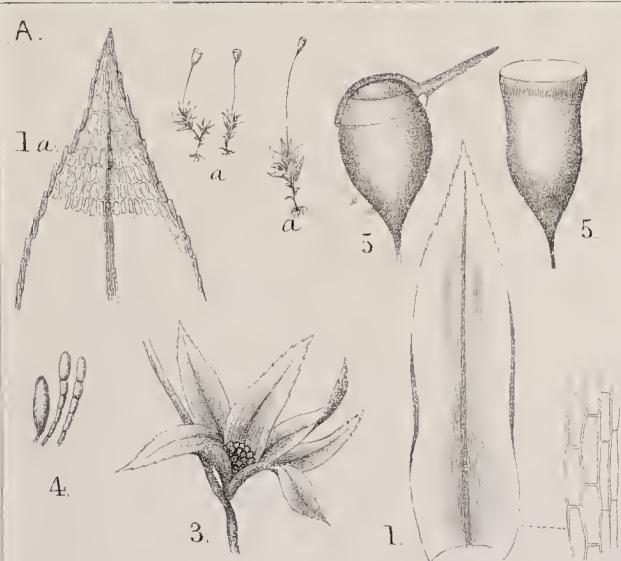

This universally distributed moss presents great variety, not only according to its locality, but at various stages in the growth of the same plants, as is admirably pointed out by Dillenius. The highly developed peristome is quite peculiar among mosses, the points of the teeth being attached to a central cibrose disc resembling the top of a thimble, which being at a lower level than the teeth, they reach by bending downward and then inward, thus forming a funnel-shaped cavity in the middle.

FAM. 15. BRYACEÆ.

Plants innovating below the inflorescence or from the base. Stem erect simple or with binate innovations below the apex, repeatedly dichotomous and fastigiate, with copious radicles. Leaves plurifarious, ovate, lanceolate or subulate, nerved and often dentate and limbate at margin; cells parenchymatous, subequal, or prosenchymatous and rhomboid towards apex, all smooth. Calyptra cucullate, smooth, narrow, fugacious. Caps. on an elongate seta, globose, ovate, or with the neck pyriform, usually cernuous or pendulous; lid mamillar, rarely rostrate; peristome double, very rarely none, rarely simple. Male infl. gemmiform or discoid. Inhabiting the ground, rocks and walls.

This large family including some 500 species, is readily recognizable so far as the great genus *Bryum* is concerned, but the species present much uniformity among themselves, and are thus difficult of determination, especially in the sterile condition. The position of the male inflorescence should be carefully looked for, as it affords much assistance in the discrimination of closely allied species.

Subf. 1. Oreadeæ. Infl. on short lateral branches near the base of the stem. Leaves small, pellucid. Caps. gibbous or symmetric; peristome simple, teeth confluent at base, becoming narrow and linear.

1. OREAS Brid.

Bry. univ. i, 380 (1826).

Calyptra narrow, cucullate. Caps. clavate-oval or pyriform, smooth, pendulous on a short arcuate seta, or taller and erect; teeth of peristome 16, narrow, remotely trabeculate, entire or foraminatae. Plants densely compacted, fastigiate, with slender innovations arising below the infl.; growing on alpine rocks. Der. *opos* a mountain.

The genus *Oreas* was founded by BRIDEL on three species—*O. Mielichhoferi*, *elongata* and *Martii*,—of these the last is a species of *Oncophorus* of the section *Rhabdoweissia*, the other two only constitute a single species and must of course retain the original generic name. Mr. Mitten unites with *Mielichhoferia*, *Leptochlæna* MONT. and *Haplomitrium* HAMPE, numbering together some 34 species, with a double or single peristome or none.

OREAS MIELICHHOFERI (Funck) Brid.

Dioicous; in compact glossy deep green tufts. Leaves small imbricated, lanceolate, serrate at apex, nerve vanishing. Caps. pyriform smooth, teeth broad at base. (T. LXVI, A.)

Apiocarpa Mielichhoferi HUEBEN. Musc. germ. 155 (1833). DE NOT. Syllab. 225 (1838).

Dioicous; in short very dense, deep green silky tufts, fuscous-black at base. Stems 2—4 in. high, slender, fastigiate. Leaves small, rather rigid, erecto-patent, imbricated when dry, lanceolate, accrescent upward, sharply serrate at apex, nerve vanishing below point, cells above narrowly linear-rhombose, laxer below. Caps. from a longish neck, oval symmetric, erect, or oblique, leptodermous, rufous-yellow, on a slender flexuose purple seta; lid shortly conic obtuse; annulus compound, revolute; teeth narrow, linear, pale yellow, nodoso-articulate, dilated and confluent at base. Male plant more slender, the infl. on short branches, gemmiform.

HAB.—Dripping rocks; rare. Fr. 8—9.

Var. β . *compacta* (Hornsch.).

Shorter, very densely compacted; stems slender, the leaves shorter, densely imbricated; capsule erect.

SYN.—*Weissia compacta* HORNSCH. HOPPE Pl. alp. exsic. Dec. 2.

Weissia elongata HOOK. Musc. exot. ii, t. 102, Br. fl. ii, 19.

Mielichhoferia nitida β . *gracilis* Bry. eur., WILSON, DE NOT. HOBK. Synop. &c.

HAB.—In the same localities as the type.

Micaceous rocks at Head of Glen Callater (*Greville* 1830) !! Liassic rocks above Ingleby Greenhow, Cleveland (*Mudd* 1862) !! Corry of Loch Ceander (*Roy* 1868) !

The variety only has been found in this country, and is remarkable for the very dense velvet-green patches. The Rev. Mr. Fergusson has found it bears a few capsules on rare occasions.

Subf. 2. Bryeæ. Inflorescence terminal. Leaves ovate or lanceolate, the cells rhomboid, rarely vermicular. Caps. pyriform or clavate; peristome double, teeth strongly barred, lanceolate.

2. STABLERIA Lindb.

Utkast till en nat. grupp. Eur. bladm. 20 (1878).

Plants slender, cæspitose, the leaves narrow, flexuose, with hexagono-rhombose areolation, calyptra cucullate. Caps. erect or inclined, from a longish neck, oblong, leptodermous, on a slender seta; lid conico-rostellate; peristome of 16 slender subremote teeth, inserted below the mouth, incurved when dry, remotely trabeculate, endostome a narrow

basal membrane with 16 filiform processes. Growing on sandstone rocks. Der.—after Mr. G. Stabler, an ardent bryologist, of Levens in Westmoreland.

The genus *Orthodontium* was founded by Schwaegrichen in 1827 on two mosses *O. julaceum* which is a *Bryum*, and *O. lineare*, an African moss, which thus forms the type of the genus, and to which he afterwards agreed that *O. gracile* should be added, and several other exotic species very similar in habit raised the number to 13. Mitten however recognized two different types among them and in 1869 (*Musci austro-amer.*) founded the genus *Apalodium*, very near to *Zygodon*, unfortunately embracing the original *O. lineare*, while *gracile* and others were retained under *Orthodontium*. The punctilious Lindberg restored *Orthodontium* to *lineare*, and re-named the Bryaceous genus *Stableria*.

STABLERIA GRACILIS (*Wils.*) *Lindb.*

Autoicous; slender, sparingly branched. Leaves comant, lanceolate-subulate, flexuose, nerved, entire. Caps. nearly erect, narrowly pyriform, long-necked; lid conic, rostellate, teeth slender, endostome half their length. (T. LXVI, B.)

SYN.—*Bryum gracile* WILS. Engl. bot. Suppl. t. 2835 (1839).

Stableria gracilis LINDB. Utk. till en nat. grupp. Eur. bladm. med topps. frukt 20 (1878).

Paroicous and autoicous; in small subpulvinate tufts, bright or yellowish-green, fragile, sparingly branched from base. Lower leaves minute, lanceolate, upper crowded in a coma, soft, flexuose, elongate lanc.-subulate, cells narrow sublinear above, at base lax, hexagono-rectangular hyaline, margin plane, nearly entire, often undulate, nerve vanishing at apex. Antheridia in axils of comal leaves, paraphysate, or gemmiform. Caps. on a slender pale red seta, erect or oblique, slender oval with a long neck, leptodermous, pale yellowish, cernuous when dry and empty, sulcate, obconic, wide-mouthed; lid conic, rostellate; teeth subirregular, pale, inflexed when dry, perforated here and there in the middle line, processes of endostome much shorter.

HAB.—Sandstone rocks and black earth; rare. Fr. 3.

Helsby, Frodsham and Alderley edge, Cheshire (Wilson 1833)!! Harrison's rocks, Tunbridge wells (Borrer 1844)!! High rocks (Reeves). The Strid, Wharfedale (Spruce). West Kilbride, Ayrshire (Boyd 1887)!!

Besides the British stations, it has only been found at two localities in Finistère, France. The Abyssinian plant referred to it, has been named by Mueller *O. aethiopicum*.

3. LEPTOBRYUM Wils.

Bry. brit. 219 (1855).

Plants annual, innovating only at base, slender simple. Leaves narrow, flexuoso-subulate with a broad nerve, cells lax rectangulo-hexagonal at base, above linear-rhomoid. Calyptra narrow, cucullate. Capsule pendulous, leptodermous, long-necked, vernicose, peristome bryoid. Der. $\lambda\epsilon\pi\tau\sigma$ slender, $\beta\rho\nu\nu$ a moss.

A small genus of 3 species, another—*L. tenuinerve* SPRUCE—coming from the Andes, and the third *L. robustum* from Australia. Its mode of growth and general habit alone separate it from *Pohlia*.

LEPTOBRYUM PYRIFORME (L.) Wils.

Synoicous; in dense silky patches. Upper leaves comant, elongated, linear-setaceous, nerve half width of base, reaching nearly to apex. Caps. pendulous, pyriform, glossy. (T. LXVI, C.)

HOBK. Syn. 106 (1873). JURATZ. Laubm. oester.-ung. 246 (1882). LESQ. JAMES Moss. N. Amer. 215 (1884). HUSN. Musc. gall. 221, t. 60 (1888).

Synoicous; laxly cæspitose, soft, silky bright green. Stem $\frac{1}{2}$ —1 in. high, very slender, with slender innovations from the base; lower leaves distant, narrowly lanc., upper crowded in a coma, much longer, from a lanc. base, subulate, flexuose, margin serrated at point, cells above very narrow, long, linear, broader below; nerve dilated at base, excurrent. Infl. subcapituliform, synoicous, paraphyses numerous, acute, bracts

subvaginant and broader at base, suddenly narrowed and patent; caps. on a very slender flexuose reddish seta, inclined or pendulous, lepto-dermous, from a longish neck, oval-globose or pyriform, glossy, golden-yellow and castaneous; annulus broad, revolute, lid convex, apiculate; teeth pale yellow, lanceolate, processes of endostome keeled, gaping and perforated in the middle, with long appendiculate cilia.

HAB.—Shady rocks and walls, and sandy or turf-y soil. Fr. 5—6.

This elegant moss has leaves closely resembling those of *Dicranella heteromalla*, and what appear to be male plants may be seen in the tufts, which on dissection, however, will be found to contain abortive archegonia as well as fertile antheridia.

4. POHLIA Hedw.

Musc. frond. i, 96 (1787).

Stem slender, innovating from the base. Leaves lanc., generally glossy, the uppermost narrower and suddenly elongated, nerve terete, cells at base rhomboidal, above narrow, linear or rhomboido-hexagonal. Calyptra very narrow and fugacious. Caps. with a long neck and clavate or with a shorter neck and pyriform; peristome bryoid.—Der. after Dr. Pohl of Dresden.

This genus is by C. MUELLER and MITTEN retained as a section of *Bryum*, from which it differs only in the slender habit of the species, and their narrow elongated comal leaves with narrow or linear cells in the upper part. The name *Webera* is generally used for the genus, and was applied by HEDWIG to *Bryum nutans* and *pyriforme* in the same volume of his work, as, however, it was preoccupied by EHRHART in 1770 (see Moss-Flora i, 291), *Pohlia* must be adopted in its place. About 50 species have been referred to this genus.

CLAVIS TO THE SPECIES.

Sect. 1. EUPOHLIA.	Upper leaves suddenly elongated, dull green. Capsule narrow, with a long neck. Cilia none or rudimentary.	
Autoicous.		<i>acuminata.</i>
Paroicous.	Neck of capsule shorter than sporangium.	<i>polymorpha.</i>
	— long as sporangium.	<i>clongata.</i>
Sect. 2. LAMPROPHYLLUM.	Upper leaves broader, glossy green. Capsule pyriform, with a short neck; cilia well developed.	
Polyoicous.		<i>cruda.</i>
Paroicous.	Leaves ovato-lanceolate, nearly entire.	<i>cucullata.</i>
	— lanceolate, serrulate at apex.	<i>nutans.</i>
Diocious.	Capsule exannulate, turbinete when old.	
	Small, pale yellowish green.	<i>carnnea.</i>
	Robust, glaucous green.	<i>albicans.</i>
	— annulate, oblong when old.	
	Leaves oval, obtuse.	<i>Ludwigii.</i>
	— lanceolate, pointed.	
	Upper leaves nerved to apex.	<i>annotina.</i>
	— not nerved to apex.	
	Stem strong; leaves soft, erecto-patent.	<i>commutata.</i>
	— filiform, leaves rigid, appressed.	<i>gracilis.</i>

Sect. I. EUPOHLIA. Plants slender, lower leaves very small remote, upper long narrow comant, dull green or slightly glossy, with linear-rhomboïd cells. Caps. with a long neck, oblong, membrane of endostome narrow, processes nearly entire, without cilia, or rarely with short ones.

I. *POHLIA ACUMINATA* Hornsch.

Autoicous; densely tufted, rigid. Comal leaves long straight lineal-lanc., serrate at apex, nerved to point, margin reflexed below. Caps. horizontal on a long seta, from a long neck, cylindric-pyriform; lid acutely conic. (T. LXVI, D.)

SYN.—*Pohlia acuminata* HORNSCH. Flora ii, P. II, 94 (1819). FUNCK Moost. 40, t. 26 (1821). FICIN. Fl. Dresd. ii, 66 (1823). BRID. Bry. univ. i, 610 (1826). WALLR. Fl. cr. germ. i, 220 (1831).

Laubm. oester.-ung. 247 (1882). LESQ. JAMES MOSS. N. Amer. 216 (1884). HOBK. Synops. 2 ed. 153 (1884). HUSN. Musc. gall. 226, t. 60 (1889). LIMPR. in RABENH. Deutsch. kr. fl. Laubm. ii, 234 (1892).

Autoicous; densely cæspitose, rigid, rather glossy green, fuscous at base. Lowest leaves ovate acute, accrescent upward, comal erect, long ovato-lanc., very acute, serrate at apex, the margin reflexed below, nerve rather strong vanishing in the apex, or excurrent, upper cells narrow linear, slightly flexuose. Caps. horizontal, on a long reddish seta arcuate at top, with a long neck, clavato-pyriform, pale fuscous; lid acutely conic or subrostellate, red at base; annulus compound; peristome large, ferruginous; processes of endostome very narrow, long as teeth, without cilia. Male infl. gemmiform below the female, bracts ovate.

HAB.—Banks and stony places in the higher mountains. Fr. 8.

Ben Nevis and Ben Cruachan (*Hooker*)! Craig Challeach and Ben Lawers (*Hooker*)!! Teesdale (*Spruce*). Twll du (*Wilson* 1821)! Brandon Mtn., Kerry (*Wilson* 1828)! Toole's rocks, Wicklow (*Moore*). Glen Prosen (*Fergusson*). Ben Laoigh (*Ewing*).

This and the two following species are very closely allied, and they depend for their stability as species principally on the position of the male reproductive organs. Whether this may be invariable or not may be open to doubt, as we find in some other mosses it is not always reliable.

2. *POHLIA POLYMORPHA* Hornsch.

Paroicous; laxly tufted. Comal leaves oblong-lanc., sharply serrate at apex, nerve vanishing at point. Caps. from a shorter neck, oval-oblong, horizontal, lid conic, muticous. Antheridia axillar. (T. LXVI, E.)

SYN.—*Pohlia polymorpha* HORNSCH. Flora ii, P. II, 94 (1819). FUNCK Moost. 42, t. 27 (1821). BRID. Bry. univ. i, 619 (1826).

Lamprophyllum elongatum LINDB. Revis. crit. ic. fl. dan. 27 (1871).

Paroicous; in small tufts or gregarious, stems $\frac{1}{2}$ —1 in. high, simple, pale silky green. Comal leaves elongato-lanc., erecto-patent, acute, more or less sharply serrate at apex, margin recurved below middle, nerve stout, vanishing at or below apex, cells above linear-rhomboïd or subvermiform, basal narrow hexagono-rectangular. Caps. on a long purple seta, suberect or inclined, very narrow, elongato-elliptic, with the neck longer than the sporangium, pale cinnamon-brown; when dry and deoperculated, ascending, slightly constricted below the mouth; lid orange, acute or slightly rostellate, teeth lanceolate-subulate, yellowish, processes of endostome punctate, entire, cilia two, short or rudimentary.

HAB.—Rocks and gravelly banks in subalpine places; not uncommon. Fr. 8.

An elegant species, readily known by its clavate capsule and the most distinct of these three closely allied plants, although some forms occur with a shorter capsule which approach the other two more nearly. *Pohlia longicollis* (SWARTZ) is also allied, and may be found in the north, as it occurs in Norway and Lapland; it is a more robust plant with larger and broader leaves, the capsule with a shorter, thicker neck, and endostome well-developed.

Sect. 2. LAMPROPHYLLUM. Leaves broader, more laxly areolate, the comal less suddenly elongate. Caps. thicker, with a short neck, membrane of endostome broader, with cilia.

4. **POHLIA CRUDA** (*L.*) *Lindb.*

Polyoicous; cæspitose. Lower leaves ovato-lanc., upper linear-lanc., patent, serrate at apex. Caps. cernuous, oblong-pyriform with a short neck, cilia perfect. (T. LXVII, A.)

Lamprophyllum crudum LINDB. Revis. crit. ic. fl. dan. 87 (1871).

Pohlia cruda LINDB. Musc. Scand. 18 (1879).

Autoicous, sometimes dioicous, paroicous or synoicous; cæspitose, erect 1—3 in. high, with simple reddish stems. Lower leaves broadly ovato-lanc., entire with plane margins, gradually accrescent upward, comal patent, long linear-lanc., remotely serrate at apex, all golden glossy or glaucous green, with the nerve red at base, vanishing below apex; cells firm, narrow and elongated. Caps. cernuous or horizontal, on a flexuose reddish seta, leptodermous, oblong-pyriform, often ventricose, with a short neck, before sporing fuscous-yellow, when empty pale brown, narrowed at mouth; lid convex, apiculate, peristome pale yellow, cilia 2—3 perfect, half the length of processes.

HAB.—Clefts of rocks and sandy banks in mountains. Fr. 7—8.

An elegant moss frequent in Scotland and growing especially fine and abundant in Teesdale, where it adorns the scarrs with its golden glistening tufts.

5. **POHLIA CUCULLATA** (*Schwaeg.*) *Bruch.*

Paroicous; densely cæspitose, bright green. Lower leaves broad ovato-lanc. rather obtuse, comal narrow, lanc., serrate at apex. Caps. on a short seta, pendulous, oval, thickish with a short neck, lid small, conic, obtuse. (LXVII, B.)

Lamprophyllum cucullatum LINDB. Rev. crit. icon. fl. dan. 87 (1871).

Paroicous; densely cæspitose, fastigiate, bright green. Stems generally decumbent at base, erect, simple or sparingly branched, radiculose. Lower leaves subimbricated, ovate, concave, muticous, entire, upper longer, narrow lanc., with the margin scarcely revolute, faintly serrate at apex, and not unfrequently cucullato-incurved, all very soft, subopake, with thickish vanishing nerve, cells rhombic, narrow, elongated. Caps. pendulous, on a shortish flexuose red seta hooked at top, thickish, with the neck shortly pyriform, when dry and empty not contracted below the mouth, but with the orifice narrowed, soft, badious, when old black-brown; lid small orange, conic, obtuse; teeth narrow, shorter, yellowish, inner very slender pale, cilia fugacious.

HAB.—Damp ground on mountains, rare. Fr. 8.

Mountains in Arran (*Borrer*)! Ben Attow, Ross-shire (*Dixon* 1883) !!

This moss is very near *P. nutans*, but is scarcely glossy, the leaves often cucullate at apex, their cells looser and thin-walled.

6. **POHLIA NUTANS** (*Schreb.*) *Lindb.*

Paroicous; densely cæspitant, shining green. Lower leaves ovato-lanc., entire, upper gradually longer, lineal-lanc., serrate at apex. Caps. pendulous, oval-pyriform with a wide mouth, lid mammillate. (T. LXVII, C.)

Lamprophyllum annotinum LINDB. Rev. crit. icon. fl. dan. 75 (1871).

Pohlia annotina LINDB. Musc. scand. 18 (1879).

Dioicous; loosely tufted, pale or yellowish-green. Stem red, erect, branched at base. Leaves lanceolate, small and distant below, accrescent upward, comal elongated, erecto-patent, serrulate at point, the margin reflexed in lower half, nerve reaching nearly to apex; cells narrow, linear-rhomoid, basal purple, wider, hexagono-rectangular. Caps. on a pale red seta, pendulous, narrowly pyriform with a long neck, pruinose, pale yellowish-red, finally reddish-brown and contracted

below the mouth; annulus compound, lid conical, pointed, orange; peristome yellowish, membrane of endostome half as high as the teeth, processes gaping, cilia 2, rough.

Male infl. terminal, gemmiform, bracts spreading, lanceolate, pointed. Sterile branches with numerous red axillar gemmæ, by which the plant is commonly propagated.

HAB.—Sandstone cuttings and sandy banks. Fr. 5—6.

Var. β . *tenuifolia* Schimp. Synops. 2 ed. 401.

Slender, the sterile branches longish and generally free from gemmæ; upper leaves oblongo-lanc., sharply serrate at apex, lower subpatent, ovato-lanc., the cells laxer; caps. pale with narrower teeth.

HAB.—Wet sandy places with the type.

Var. γ . *angustifolia* Schimp. Synops. 2 ed. 401.

Sterile branches numerous slender flexuose; comal leaves longer, narrower, lanc.-subulate, obsoletely serrate at apex, the nerve subexcurrent, the lower narrowly lanc., cells thin and narrow.

HAB.—Sandy bogs near Warrington (*Wilson*).

The fruit is rare, but the gemmiparous state is frequent, and the gemmæ in wet places often pass into small leafy bulbils, which are readily detached from the plants.

9. **POHLIA LUDWIGII** (*Spreng.*) Lindb.

Dioicous; tufted, from a decumbent base, erect, red below, deep green above. Leaves decurrent, broadly obovate, obtuse, comal oblongo-lanc., serrulate at apex, recurved at margin; nerve vanishing. Caps. inclined, oval-oblong; lid mammillar. (T. LXVIII, B.)

SYN.—*Bryum Ludwigii* SPRENG. MSS. SCHWAEG. Suppl. I, P. II, 95, t. 68 (1816). BRID. Bry. univ. i, 647 p.p. (1826). HOOK. Br. fl. 59 (1833). WILS. Eng. Bot. Suppl. t. 2855 (1841), Bry. br. 228, t. 47 (1855). BOUL. Musc. de Fr. i, 279 (1884).

Bryum Schimpéri WILS. MSS.

Bryum catenulatum SCHIMP. SYNOPS. 2 ED. 471.

Pohlia commutata LINDB. MUSC. SCAND. 17 (1879). CARDOT IN REV. BRYOL. 1886, p. 28.

Dioicous; resembling *P. Ludwigii* but smaller, tufts dense, yellow-green above, fuscous or blackish at base, the stem red, sparingly

radiculose. Leaves smaller, softer, erecto-patent when moist, imbricated and somewhat incurved when dry, glossy, scarcely decurrent, carinate at back, lower ovato-lanc., upper larger oblongo- or lineal-lanc., more or less serrate at the pointed apex; nerve strong, vanishing, margin plane or reflexed at base; cells narrower, hexagono-rhomboïd. Caps. on a shorter red seta, smaller oval-oblong or pyriform, pale brown, lid conic, apiculate. Male plants more slender, simple; bracts ovato-lanc.

HAB.—Wet peaty soil on the higher mountains, rare. Fr. 8.

Ben Lawers (*Wilson* 1836)!! Ben Lomond (*Stirton* 1865)! Snowdon (*Hunt* 1865)! Crow Road, Campsie (*Hunt* 1866)!! Lochnagar (*Hunt* 1868)!

Long confounded with *P. Ludwigii*, but differing in the leaves which are scarcely decurrent, narrower, more pointed, more distinctly serrated and carinate at back. Schimper's *Bryum catenulatum* appears to be only a stouter more rigid form, with the leaves incurved when dry, and his *Bryum filum* an extremely attenuated variety.

II. POHLIA GRACILIS (*Schleich.*) *Lindb.*

Dioicous; stems filiform, loosely tufted. Leaves small, erect, ovate, pointed, faintly serrate at apex, upper longer and more acute, nerve vanishing below point. Caps. pendulous, small, ovate, lid apiculate. (T. LXVIII, D.)

SYN.—*Bryum gracile* SCHLEICH. Catal. pl. helv. 4 ed. (1821).

Bryum Ludwigii β . *gracile* BR. SCH. Bry. eur. fasc. 6—9, p. 39, t. 14 β . (1839). C. MUELL. Synops. i, 333 (1849).

Pohlia gracilis LINDB. Musc. scand. 17 (1879).

Bryum commutatum β . *gracile* BOULAY Musc. Fr. i, 279 (1884).

Dioicous; much more slender than *P. commutata*, in loose yellow-green, glossy tufts, blackish at base, with many rigid filiform shoots, short in the fertile plants, elongated and often with red axillar gemmæ in the sterile. Leaves erect, appressed when dry, rigid, ovate and ovato-lanc., short-pointed, without chlorophyl, margin plane, faintly serrate at apex; nerve thinner lost at or below the point. Caps. turgidly ovate, cernuous, small, reddish-brown, lid orange, hemispherical, apiculate.

HAB.—Mountain rocks, very rare. Fr. 8.

Ben Lomond sterile (*Dr. Stirton* 1865) !

This is certainly distinct from *P. commutata* and fruits freely when at home, as by the glacier streams in Lapland and the Swiss Alps.

12. POHLIA ALBICANS (*Wahlenb.*) *Lindb.*

Dioicous; in pale glaucous green tufts with red stems. Leaves subdecurrent, lanceolate, lower ovato-lanc., upper lanc. acuminate, serrate at apex. Caps. pendulous, pyriform, exannulate, lid conic. (T. LXVIII, A.)

HAB.—In more mountainous places.

Loch Brandy, Clova (*Braithwaite* 1864)!! Ben Lawers (*Hunt* 1865). Canlochan, Braemar (*Hunt*)!! Mael Girty (*Whitchead* 1875).

Much more robust than the type, resembling *B. turbinatum* Var. *latifolium*, and rarely producing fruit.

5. EPIPTERYGIUM Lindb.

Oefv. vet. ak. foerhandl. xix, 603 (1862).

Small mosses inhabiting wet clay banks and resembling in habit some species of *Mnium*. Leaves—especially in the sterile plants—of two forms, unequal, two lateral rows large distichous and somewhat complanate, two or three anterior rows minute stipuliform. Infl. and fruit as in *Pohlia*.—Der. $\epsilon\pi\iota$ upon, $\pi\tau\epsilon\rho\nu\gamma\iota\omega$ a little wing.

Elegant mosses of peculiar habit which fairly entitles them to generic distinction. A second and larger species—*E. Jamaicense* LINDB.—is found in the West Indies.

EPIPTERYGIUM TOZERI (Grev.) Lindb.

Larger leaves decurrent, oboval, acutely acuminate, with a narrow reddish border; smaller suberect, minute distant lanceolate, in two rows. (T. LXVIII, E.)

SYN.—*Bryum Tozeri* GREV. Scott. cr. fl. v. t. 285 (1827). HOOK. Br. fl. ii, 65 (1833). BR. SCH. Bry. eur. fasc. 6—9, p. 41, t. 16 (1839). C. MUELL. Synops. i, 298 (1849). WILS. Bry. br. 249, t. 50 (1855). BOUL. Musc. de Fr. i, 283 (1884). LESQ. JAMES Moss. N. Amer. 222 (1884).

Epipterygium Tozeri LINDB. l.c.

Anisostichium Tozeri MITT. Journ. Linn. soc. vii, Bot. 119 (1863).

Dioicous; plants gregarious, small soft pale green, reddish at base, with a few slender branches and purple radicles. Lower leaves distant obovate, acutely acuminate, longly decurrent, upper more crowded,

broader, narrowed at base, quite entire, nerve reddish, reaching middle, often forked, all with a reddish limb of several rows of very narrow cells, the other cells lax rhomboido-hexagonal, or 5—8 angled; those of the anterior rows remote minute lanceolate. Perich. bracts small, lanc., caps. pendulous on a red seta geniculate at base, obovate with a short neck, soft pale brown, rufescent, wide-mouthed when old; lid conic rufous, annulus of many series of cells; teeth small, reddish-yellow, endostome thin, hyaline, with 1—2 short cilia. Male plant more slender, upper leaves acuminate-ligulate, perig. bracts oval-oblong, nerve obsolete.

HAB.—Wet clay banks and by streams, rare. Fr. 3—4.

By the Dart, Devon (*Tozer*)! Penzance (*Ralfs*)!! Torquay (*Miss Griffiths*). Henfield (*Borrer*). Near Hurstpierpoint (*Mitten*)! Swanscombe Wood, Kent (*Johns*)! Plymouth and Buckfastleigh (*Holmes* 1867)!! By the Lee, Cork (*Alexander* 1840). On the Wye at Breinton (*Ley*).

6. PLAGIOBRYUM *Lindb.*

Oefv. vet. akad. foerh. xix, 606 (1862).

Plants short in small tufts, the leaves resembling those of *Bryum*, laxly areolate, closely imbricated. Caps. horizontal or decurved, gibbous, with a very long narrow neck, the mouth oblique; calyptra cucullate, peristome as in *Pohlia*.—Der. $\pi\lambda\alpha\gamma\iota\sigma$ oblique, $\beta\rho\nu\nu\sigma$ Bryum.

The name *Zieria* of Schimper cannot possibly be used for this moss, as it was adopted by Smith for a genus of Australian Rutaceæ in 1798 (Trans. Linn. Soc. iv, 216). A third species *P. leptocladon* (SULLIV.) is found in Cuba. The gibbous capsule and oblique mouth give them somewhat the aspect of *Funaria*, and the teeth of the peristome are shorter than the processes of the endostome.

CLAVIS TO THE SPECIES.

Leaves oval plane, nerve vanishing.
— lanceolate, revolute, nerve excurrent.

Zierii.
demissum.

I. PLAGIOBRYUM ZIERII (*Dicks.*) *Lindb.*

Dioicous; in short silvery pale reddish tufts with julaceous branches. Leaves ovate-acuminate, imbricated, entire, nerve vanishing below apex. Caps. clavate, subpyriform, cernuous, gibbous, mouth oblique; endostome longer than peristome, cilia imperfect. (T. LXIX, A.)

Dioicous; in dense rufescent tufts, stems very short, radiculose, with many very short innovations. Lower leaves ovate-acuminate, the nerve vanishing below apex, upper oblong-lanc., longly cuspidate with the excurrent nerve, the margin recurved, all erecto-patent, rufescent by age, cells rhombic-hexagonal above, rectangular at base. Caps. bent down on an arcuate orange seta, irregular, gibboso-pyriform, pale brown, lid small, mammillar, teeth lanceolate, ferruginous below, half the length of the processes which cohære above by transverse trabeculæ, cilia 1—2, very short. Male infl. gemmaceous.

HAB.—Rocks on the summit of the Breadalbane range. Rare. Fr. 8.

Ben Lawers and Craig Chailleach.

This fine moss only grows at the summits of the mountains in crevices of rocks filled with black humus in which the roots are deeply fixed. The position of the capsule varies with age, being at first horizontal, then bent down by the curvature of the seta until it almost touches the leaves, and when empty more or less erect.

7. BRYUM Dill.

Catal. pl. circa Gissam 222 (1719).

Plants generally with a pair of innovations below the floriferous apex, thus becoming repeatedly dichotomous, the stems interwoven with radicles. Leaves in 5 or 8 rows, semiamplexicaul, more or less decurrent, smooth, ovate or lanceolate, rarely obtuse; nerve terete, usually excurrent, cells rather lax, hexagono-rhombic, and quadrate or rectangular at base. Calyptra small cucullate. Caps. on a long wiry seta, inclined or pendulous, pyriform to subglobose with a solid neck, regular or slightly incurved, coriaceous, lid convex apiculate, annulate; peristome of 16 long lanc. teeth, densely articulated in the lower half, lamellate internally, endostome a 16-carinate membrane half the length of the teeth, with 16 lanceolate keeled processes, gaping or perforated

in the keel and 1—3 intermediate filiform cilia, generally transversely appendiculate, rarely abortive. Growing on the ground, rocks and walls, rarely on tree trunks.—Der. *βρύον* a moss.

The genus *Bryum* comprises some 400 species, varying in size, but in most cases closely allied in habit and by the form of their beautiful pear-shaped capsules. The leaves in many approximate so closely in form and structure, that in a sterile condition it is hardly possible to determine the species with certainty, as the nature of the endostome and relation of the reproductive organs must be clearly made out. The former is best attained by soaking the capsule, cutting off the peristome and laying it flat in water between two slides.

The formation of the endostome has been used to characterise some other sections of the genus, thus in *Brachymenium*, it is reduced to a simple erose membrane about half as high as the teeth, and in *Acidodontium* the processes are cleft into two divergent segments; but after all these groups are purely artificial, and though most useful in hunting up species, they often separate far apart some which are closely allied, e.g., *B. fallax* and *B. pallens*. Again, we may notice a close relationship among certain species and yet be quite unable to define it in words, as in *B. argenteum*, *bicolor*, *erythrocarpum*, *murale*, *marginatum*, *Mildei*, &c., or in *B. lacustre*, *Marratii*, *turbinatum*, *calophyllum* and *Warneum*, and there is a *capillare* group, and most distinct of all that marked by *B. proliferum*; continued observation of the living plants in the field of Nature may eventually clear away some of the difficulties which at present beset our path.

CLAVIS TO THE SPECIES.

Sect. 1. SCLERODONTIUM. Shoots filiform, julaceous with appressed coriaceous leaves, the upper cells linear.

Leaves obtuse, the nerve vanishing. — pointed, nerved to apex.	<i>filiforme.</i> <i>concinnatum.</i>

Bryum (Anomobryum) filiforme SCHIMP. Syn. 2 ed. 465 (1876).

Anomobryum filiforme HUSN. Musc. gall. i, 222, t. 60 (1888). LIMPR. in RABENH. D. kr. fl. Laubm. ii, 218 (1892).

Dioicous; in tallish glossy pale green tufts, the branches long and filiform, with densely imbricated leaves. Leaves not altered by moisture, ovate or oval-oblong, obtuse, very concave, margin erect, entire or minutely serrulate at apex, nerve yellow, vanishing at summit, cells variable, upper flexuoso-linear or narrowly rhomboid, incrassate, lower laxer and thinner, hexagono-rectangular. Perich. bracts longer, ovato-lanc., muticous and acute. Caps. on a reddish seta arcuate at top, inclined or subpendulous, oval or narrowly oblong with an attenuated neck, usually a very little incurved, pale reddish or castaneous, scarcely contracted below the mouth when dry; lid high, convex with a short papilla, rufous, very glossy, annulus compound, separating spirally; teeth light ferrug. below, subulate and hyaline above, endostome yellowish, the processes lacunose, with 1—3 longly appendiculate cilia. Male plant very slender, the infl. gemmiform, bracts roundish, nerveless.

HAB.—Wet places among rocks in alpine districts. Fr. 8—9.

Frequent on the mountains of Scotland, Wales, and N. of England, and about Killarney, Ireland, the leaves quite of different texture from those of *B. argenteum*, for which it has several times been mistaken.

2. *BRYUM CONCINNATUM* Spruce.

Dioicous; smaller than *B. filiforme*. Leaves ovate acute, nerved to apex, the cells narrow linear-hexagonal. (T. LXIX, D.)

SYN.—*Bryum concinnatum* SPRUCE in Trans. bot. soc. Edin. iii, 155 (1849). C. MUELL. Synops. ii, 575 (1851). HARTM. Sk. fl. 9 ed. ii, 34 (1864). SCHIMP. Synops. 2 ed. 468 (1876). JURATZ. An. julaceum Var. β . *concinnatum* ZETT. Musc. pyr. 34 (1866).

Bryum filiforme Var. *concinnatum* BOUL. Musc. de Fr. i, 294 (1884).

Dioicous; filiform, in dull silky green tufts often obscured by muddy deposit. Leaves densely crowded, imbricated, sometimes with axillar bulbils, ovate or elliptic, less concave, more or less acuminate with a short recurved acute apiculus, entire or obsoletely denticulate at apex; nerve yellowish, lost in the point, cells laxer, narrowly hexagono-rhomboidal, indistinctly curved.

HAB.—Dripping subalpine rocks, rare. Fr. unknown.

Caldron Snout, Teesdale (*Spruce* 1843)!! Knockavohila, Kenmare (*Taylor*). Ochil hills ♀ (*Lyle* 1849)! Black Force, Yorks. (*Binstead* 1886)!! Kisdon Force, East Gill and West Stonesdale beck in Upper Swaledale (*R. Barnes* 1889)!! Stanner rocks, Radnor (*Binstead* 1892)!!

A softer plant than *B. filiforme*, readily known by the acutely pointed leaves which are not closely appressed but divergent at point.

Sect. 2. CLADODIUM. Leaf-cells hexagono-rhombic; endostome adherent to teeth of peristome or free and without cilia, or with short exappendiculate cilia.

3. **BRYUM LACUSTRE** (*Bland.*) *Brid.*

Synoicous; stem short, branched. Leaves ovate, acute, concave, with recurved margins, nerved to apex. Caps. pendulous, pyriform, lid small apiculate. (T. LXIX, E.)

SYN.—*Mnium lacustre* BLAND. Musc. exsic. n. 132 (1804). ROEHL. Deutsch. fl. iii, 96 (1813). SCHWAEG. Suppl. I, P. II, 124, t. 79 (1816). SCHULTZ Suppl. Fl. Starg. 86 (1819).

Bryum Webera lacustris BRID. Bry. univ. i, 636.

Pohlia lacustris HUEB. Musc. germ. 483 (1833).

Synoicous; widely tufted, the stems short, radiculose, branches longer. Leaves rather solid, chlorophyllose, lower small distant, broadly ovate, acuminate, upper suddenly larger, forming a patent coma, broadly oblong, acutely acuminate, carinate-concave, margin entire not thickened, broadly reflexed; nerve strong, rufous, vanishing below the apex or excurrent in an apiculus, cells scarcely thickened. Vaginula thick, covered with paraphyses; fruit varying in size and length of seta in the same tuft, caps. small, on a long slender seta, inclined or rarely pendulous, oblong-pyriform, slightly incurved, soft, pale brown with a

darker neck; annulus broad, lid conical; per. small yellow, membrane of endostome not reaching middle of teeth, processes widely gaping, with 2 rudimentary cilia.

HAB.—Wet sandy places, not common. Fr. 6—7.

Yarmouth (*Turner*). Wangford, Suffolk (*Eagle* 1804)! Freshfield and Ainsdale, Southport (*Hunt* 1860)!! Taunton, Ashton-under-Lyne (*Schimpfer* 1865)!! Coatham marshes, Yorks. (*R. Barnes* 1891)!!

This moss is generally found along with *B. calophyllum*, *Warneum* and *Marratii*, and appears to indicate that all have sprung from some common ancestor.

4. **BRYUM INCLINATUM** (*Sw.*) *Bland.*

Synoicous; cæspitose, stem short, sparingly branched. Leaves spreading, ovato-lanceolate, entire, nerve excurrent. Caps. pendulous, ventricose-pyriform with a small mouth. (T. LXIX, F.)

SYN.—*Pohlia inclinata* SWARTZ Musc. suec. 45 et 96, t. 5, f. 11 (1798). BRID. Musc. rec. II, P. III, 144 (1803), Sp. musc. III, 76 (1817), Mant. 115 (1819). SCHULTZ Fl. starg. 354 (1806). SCHWAEG. Mnium intermedium Var. ROEHL. Deutsch. fl. iii, 93 (1813).

Bryum turbinatum Var. HOOK. TAYL. Musc. br. 122 (1818).

Cladodium inclinatum BRID. Bry. univ. i, 621 (1826).

Synoicous; very like *B. pendulum*. Leaves softer, subrevolute, rather more widely limbate, acutely carinate toward apex, nerve rufous, excurrent in a toothed hair. Caps. on a long purple seta, inclined or pendulous, from a longer neck, ovate or oblong, often a little incurved, somewhat contracted below the mouth when dry, rufo-fuscous or badius, annulus broad, lid from a convex base broader with a shorter point; endostome free above, the membrane half the length of the teeth, processes long free, perforated in the keel, cilia none.

HAB.—On walls and banks, not uncommon. Fr. 5.

Differs from *B. pendulum* by the more lanceolate leaves with broader limb, caps. more slender and symmetric with a wider lid. From *B. cæspiticium* by the endostome and inflor. as well as small mouth of capsule, and less silky leaves. *B. longisetum* BLAND. appears to be only a variety.

5. **BRYUM PENDULUM** (*Hornschr.*) *Schimp.*

Synoicous; compactly tufted. Leaves ovate acuminate, concave, recurved at margin, nerve excurrent. Caps. ventricose pyriform with a small mouth, endostome adherent. (T. LXX, A.)

Laubm. ii, 293 (1892).

Synoicous; sometimes also with gemmiform male infl. intermixed; densely cespitant and tomentose, dull green with short branches. Comal leaves densely crowded, erecto-patent, ovato-lanc., carinate concave, the nerve stout, far excurrent, margin more or less reflexed, narrowly limbate, serrulate or entire at extreme apex, all rather rigid; cells dense, rhombic above, rectangular and red at base. Caps. rich brown, pendulous, from a neck swollen at base shorter than the sporangium, oval or ovato-globose, slightly contracted below the mouth, shorter or longer, lid rather small, broadly conic, acutely apiculate; annulus broad; teeth of peristome reddish-yellow at base, and according to Husnot traversed on the back by many fine sinuous lines, endostome adherent, the processes only partly free, cilia rudimentary.

HAB.—On walls, rocks and waste ground; not uncommon. Fr. 5.

Very variable in size and form of capsule and differing from *B. inclinatum* by the broader leaves and more ventricose capsule with adherent endostome, and from *B. cespiticium* by the small mouth of capsule, the infl. and endostome.

6. **BRYUM PURPURASCENS** (*R. Br.*) *Br. Sch.*

Synoicous; plants slender dull green, purplish at apex. Leaves ovato-lanc., mucronate with the excurrent nerve, narrowly limbate, slightly recurved at margin. Caps. pendulous, oblongo-pyriform, lid hemispherical, cilia imperfect. (T. LXXII, A.)

SYN.—*Pohlia purpurascens* R. BR. Suppl. App. to Parry's Voy. 197 (1824).

Bryum fuscum FERG. in Naturalist N.S. V, 82 (1880). HOBK. Synops. 2 ed. 157 (1884).

Synoicous or heteroicous, in loose tufts, dull green below, purplish at apex. Stems slender with innovations from below the perichaetium which are sometimes flagelliform, with a few small leaves. Lower leaves ovate, acute, upper oblongo-lanc., patent, twisted when dry, mucronate with the excurrent yellow nerve, concave, narrowly limbate, margin slightly recurved, entire or with 1—2 irregular teeth at apex; cells at base rectangular, above rhombo-hexagonal. Perich. bracts lanc., more acuminate; seta red, bent suddenly at top. Caps. pendulous, oblong-pyriform with the neck shorter than sporangium, regular, pale fuscous, rufescent at neck; annulus large, lid small hemispherical, mammillar, of the same colour as caps., peristome yellow, processes of endostome free, lanc.—subulate, cleft, cilia imperfect.

HAB.—Crevices of limestone rocks, very rare. Fr. 7. Near Litton, Yorks. (Whitehead 1879)!

The single plant sent by Mr. Whitehead quite agrees with Norwegian specimens of this scarce moss, except that it is more stunted and consequently the stem, leaves and capsule are shorter. Another closely allied species (*Br. arcticum* R. BR.) is more frequent in Scandinavia than the present one and is not unlikely to occur here; it has more acuminate leaves, with longer points, and a ferruginous border.

7. BRYUM WARNEUM Blandow.

Autoicous; in small tufts with few branches. Leaves oblong, acuminate, with a narrow border, plane above. Caps. pendulous, ventricose-pyriform with a small mouth. (T. LXX, B.)

Autoicous; in loose incoherent soft pale green tufts; stem short, simple or branched, with few radicles. Stem-leaves remote, orbicular-ovate, obtuse, comal crowded, laxly imbricated in an obtuse gemmule, broadly ovate and oval-oblong, narrowed into a short obtuse acumen; all rather succulent, very concave, margin entire, plane or slightly recurved, not limbate, nerve vanishing at or below apex, cells narrowly rectangular and rhombic-hexagonal; perich. bracts narrower, innermost lanceolate, lax-celled. Caps. on a long straight rigid red seta, geniculate at base, suddenly pendulous, shortly pyriform with a short neck, slightly contracted below the mouth when dry, ferruginous brown; peristome yellow, endostome with narrow slightly perforated processes, cilia rudimentary. Male infl. gemmiform, 1—2 at base of female.

HAB.—Wet sandy ground, rare. Fr. 9—10.

Sands at Southport (*Marrat*)!! Ashton-under-Lyne (*Gordon* 1865)!! Tent's Muir, Fife (*Howie*). Coatham marshes, Yorks. (*R. Barnes* 1891)!! Braunton Burrows, Devon (*Mitten*). Sands of Barry, Dundee (*Holmes* 1890)!!

III. **BRYUM FALLAX** *Milde.*

Dioicous; in dingy green tufts. Stem leaves obovate, carinate, short pointed, limbate, nerved to apex. Caps. pyriform, with a long neck and small mouth, cilia of endostome rudimentary. (T. LXXII, B.)

SYN.—*Bryum fallax* MILDE Bry. Siles. 209 (1869). SCHIMP. Synops. 2 ed. 426 (1876). BOUL. Musc. de Fr. i, 272 (1884). HUSN. Musc. gall. i, 238, t. 64 (1889).

Bryum pallens β. *fallax* JURATZ. Laubm. oester.-ung. 287 (1882).

Dioicous; in lax soft tufts, rufous green above, short. Stem-leaves obovate-spatulate, short-pointed, carinate, narrowly limbate, broadly recurved, nerved to the apex; comal oblong, gradually acuminate, reddish at base, twisting when dry, inner perichaetal smaller lanceolate, ramuline leaves distant, oblong-lanc.; cells rather lax, hexagono-rhombic, basal hexagono-rectangular. Caps. on a long rufous seta,

hamato-arcuate above, inclined or pendulous, pyriform, castaneous, the neck long as sporangium and sulcate when dry; annulus broad, lid small, mammillate, peristome pale yellow, teeth lineal-subulate, endostome united to peristome for half its length, processes long as teeth, gaping widely, cilia short and rudimentary. Male plants small, simple, the infl. terminal, gemmiform, enclosed in the comal leaves, inner bracts laxly areolate, without nerve or limb.

HAB.—Wet sandy heaths, rare. Fr. 7—8.

Tilgate forest, Sussex (*Mitten* 1846) !! Snowdon (*Mitten*).

This moss is closely allied to *B. pallens* and has probably been confounded with that species ; it may be known by the abortive cilia of the endostome and broad short-pointed leaves.

Sect. 3. EUBRYUM. Leaf-cells hexagono-rhombic; endostome quite free, the basal membrane elongated, with long processes and 2—4 equally long cilia, appendiculate at joints.

12. BRYUM INTERMEDIUM *Brid.*

Synoicous; caespitose. Leaves erecto-patent, ovato-lanceolate, the margin reflexed, nerve excurrent. Caps. pendulous, narrow pyriform, long-necked, lid apiculate. (T. LXX, F.)

SYN.—*Pohlia intermedia* BRID. Musc. rec. II, P. III, 144, t. 2, f. 12 (1803). SCHULTZ Fl. starg. 254 (1806).

Bryum pallescens β. *intermedium* SCHWAEG. Sp. musc. i, 61 (1830). HUEBEN. Musc. germ. 446 (1833).

Synoicous; in wide deep green tufts, densely radiculose at base, stems short, branched with short innovations. Lower leaves ovato-upper oblongo- and elongato-lanc., nerve red at base, excurrent in a long remotely denticulate point, margin entire, subrevolute, with a very narrow border. Caps. horizontal and inclined, from a neck as long as sporangium, oblongo- and elongato-pyriform, slightly incurved, rufous-brown or fuscous, lid convex-conic, acute shining. Annulus separating

in fragments; processes of endostome when dry, projected between the incurved teeth, cilia shortly appendiculate.

HAB.—Walls and shady ground. Fr. 6—9.

This may be distinguished from *B. pallescens* and *cæspiticium* by the synoicous infl., and the narrower caps. with a longer neck and narrower mouth.

13. **BRYUM BIMUM** Schreb.

Synoicous; in tall dense tufts. Leaves spreading ovato-lanc., decurrent, cuspidate with the excurrent nerve, the margin recurved. Caps. pendulous, oblong-pyriform, lid large, mammilar. (T. LXXI, A.)

Bryum pseudotriquetrum β. SCHWAEG. Suppl. I, P. II, 211 (1816).

Bryum ventricosum p.p. HOOK. TAYL. Musc. br. 124 (1818).

Synoicous; in dense shorter or taller tufts, green or olivaceous above, brown or blackish at base; stems with rufous tomentum, fastigiate-branched. Leaves semiamplexicaul, decurrent, patulous, when dry laxly imbricated and a little twisted, outer comal elliptic shortly acuminate, median oblong-lanc., shortly cuspidate with the reddish-brown excurrent nerve, lower ovate or elliptic, shortly pointed, margin revolute with a limb of 2—4 rows of narrow cells, bluntly serrate at apex. Caps. pendulous on a long seta, obovate- or oblong-pyriform, slightly constricted below the mouth when dry, ferruginous-brown, lid mammilar, large; membrane of endostome prolonged.

HAB.—Bogs and marshy ground. Fr. 6—7.

This moss was long confounded with *B. ventricosum* DICKS, but differs in the synoicous infl., the leaves also are more divergent and laxer, distinctly cuspidate, and the capsule shorter and more regular.

14. **BRYUM AFFINE** (*Bruch*) *Lindb.*

Synoicous; shorter and denser. Leaves ovato-lanc., longly cuspidate with the excurrent nerve, comal long and lanc. Caps. with a long neck. (T. LXXI, B.)

SYN.—*Webera affinis* BRUCH in BRID. Bry. univ. i, 848 (1827).

Mnium argenteum HOFFM. Deutsch. fl. ii, 51 (1795). P. BEAUV. Prodr. 74 (1805).

Bryum Barnesii SCHIMP. Synops. 2 ed. 471 (1876).

Dioicous; in irregular laxly cohering tufts, whitish-green, silvery and glossy when dry. Plants short, slender radiculose, with slender julaceous branches; leaves obovate, very concave, suddenly apiculate, laxly reticulate, comal oblong, gradually apiculate, the nerve vanishing above the middle, margin plane, quite entire. Caps. pendulous, on a seta arcuate at top, oblong, contracted below mouth when dry, rufous red, blackish when old, lid convex, scarcely apiculate, orange; teeth orange at base, yellowish above, incurved between the processes when dry. Male plant slender, perig. bracts broadly oval, apiculate.

HAB.—Waste ground, walls and rocks; common. Fr. 10—11.

Var. β . *majus* BR. SCH.

Taller, more densely matted, glaucous green; leaves submuticous, caps. scarce elevated above the branches.

SYN.—*Bryum julaceum* SCHRAD. Spic. fl. germ. 70 (1794). BRID. Bry. univ. i, 859, p.p.

Bryum argenteum Var. *majus* BR. SCH. Bry. eur. 79. C. MUELL. Synops. i, 314. WILS. Bry. brit. 247.

HAB.—In damp shady places.

Var. γ . *lanatum* (*P. Beauv.*).

Compactly tufted, branches shorter, snowy-white; leaves longly apiculate or prolonged into a flexuose hair void of chlorophyl, scariose and silvery white when dry.

SYN.—*Mnium lanatum* P. BEAUV. Prodr. 75 (1805).

Bryum lanatum BRID. Sp. Musc. III, 20; Mant. 118; Bry. univ. i, 659.

Bryum argenteum Var. *lanatum* BR. SCH. Bry. eur. C. MUELL. WILSON.

HAB.—In warm stony places; rare.

Hedge bank, Southport (*Wild* 1882)!! Mortar of a bridge near Kendal (*Binstead* 1886)!!

This common moss varies very much according to locality, and when growing in wet shady places quite loses its silvery appearance. *Bryum Barnesii* SCHIMP. appears to be only a form starved by growth among sand.

19. BRYUM BICOLOR Dicks.

Dioicous; stems short, branched, dull green. Leaves erecto-patent or appressed, ovato-lanc. or ovate, concave, margin reflexed, nerve reaching point or slightly excurrent. Caps. oval, short, constricted below the lid. (T. LXXII, D.)

SYN.—*Bryum pendulum, surculis teretibus viridibus* DILL. Hist. musc. 394, t. 50, fig. 63, A, B, E, et fig. 66, A, F, G (1741), et Herbar.

Bryum bulbilosum MONT. Ann. des sc. nat. 2 Ser. xvi, 268 (1841). C. MUELL. Synops. i, 301 (1849).

Dioicous; in dense light green patches, the stems branched, radiculose. Lower leaves small, distant, lanc., the upper crowded in a laxly imbricated coma, much larger, ovate-acuminate, concave, shortly apiculate with the excurrent nerve, margin entire, reflexed towards base, cells lax, rhombo-hexagonal, at base rectangular. Caps. on a short flexuose red seta, arcuate above, pendulous, from a swollen neck rugulose when dry, broadly oval, from reddish yellow, blood red, and finally black-purple, very slightly contracted below mouth when dry; lid large, wider than mouth of caps., convex, apiculate, blood red, shining, teeth

reddish at base. Male plant more slender, infl. gemmaceous, bracts broadly ovate, acuminate.

HAB.—On banks, roadsides and walls, often with *B. argenteum*. Fr. 5.

Globose axillary compound gemmæ are frequently seen on this plant, which is easily known by the abruptly ending base of capsule, though this is still more pronounced in the closely allied *B. versicolor* BRAUN. It varies considerably in size, and the leaves occasionally have the nerve vanishing below the point.

Var. *β. gracilellum*. Tayl. MSS.

Gemmiparous, taller and more slender. Leaves broader and more obtuse, the nerve vanishing below the apex.

HAB.—With the typical form. Not uncommon.

20. **BRYUM ERYTHROCARPON** Schwaeg.

Dioicous; stems short, leaves ovato-lanc., erecto-patent, cuspidate with the shortly excurrent nerve, serrulate at apex. Caps. pendulous, oblong-pyriform, lid sharply pointed. (T. LXXII, E.)

SYN.—*Bryum pendulum ovatum, cæspiticium et pilosum, seta bicolori* p.p. DILL. Hist. musc. 397, t. 50, fig. 66 E.

Bryum sanguineum BRID. Sp. musc. III, 28 (1817), Mant. 118 (1819), Bry. univ. i, 671 (1826). WALLR. Fl. cr. germ. i, 270 (1831). WILS. Bry. br. 243, t. 50 (1855). HOBK. Syn. br. m. 118 (1873).

Dioicous; in short loose tufts, green with a reddish or brownish tinge. Stem slender, branched, radiculose at base, sometimes with red globose axillar gemmæ. Leaves crowded, erecto-patent, or remote and patent, straight or slightly recurved, somewhat rigid, lanc. or elongate-lanc., shortly mucronate with the excurrent nerve, margin reflexed below, serrulate at apex, without any border; nerve red, vanishing below or at the point or excurrent, cells rather large, hexagonal. Caps. pendulous on a long red seta arched at top, oblongo- and obconic-pyriform, brown or deep red; annulus broad, lid large, convex-conic,

sharp-pointed purple, shining; teeth pale ferruginous, endostome pale, with 2—3 cilia. Male plant more slender, infl. terminal, thick and gemmiform, internal bracts broadly obovate, cuspidate.

HAB.—Gravelly and sandy heaths and on walls. Fr. 6—7.

This species is closely allied to *B. bicolor* Dicks., but the fruit is larger and more tapering into the seta, and the leaves more attenuated at points. The seta varies considerably in length, and the capsule in colour from a light rusty brown to the deepest purple red.

21. **BRYUM MURALE** Wils.

Dioicous; densely tufted, leaves shorter lanceolate, with small narrow cells, entire, nerve excurrent in a long point. Caps. pendulous, pyriform with a tapering neck, and large obtuse lid. (T. LXXII, F.)

SYN.—*Bryum erythrocarpum* Var. β . *murorum* SCHIMP. Synops. 363 (1860).

Bryum murale WILS. MSS. MILDE Bry. siles. 213 (1869). HOBK. Synops. 118 (1873). SCHIMP. Synops. 2 ed. 437 (1876). JURATZ. Laubm. oest.-ung. 271 (1882). BOUL. Musc. de Fr. i, 251 (1884). HUSN. Musc. gall. 244, t. 66 (1889).

Dioicous; in dense pulvinate cæspitose tufts, green above, brownish green when old, interwoven with dense tomentum; stem short, fastigiate-branched. Leaves erecto-patent, when dry imbricated, rather rigid, the upper crowded into a gemmiform coma, lower comal longish lanc., inner from a broad base, lanceolate, lower crowded, shorter, not limbate, a little reflexed at margin, entire at apex, all longly cuspidate with the excurrent rufous nerve; cells smaller and more linear than in *B. erythrocarpon*, rhomboid-hexagonal, at base rectangular. Caps. on a dark purple seta arched at top, pendulous, with the neck clavato-pyriform, regular or slightly arched, blood-red, blackish by age; lid large, almost hemispherical, obtuse or with a very small apiculus, purple, shining, annulus broad; teeth large, endostome yellowish, the processes perforated, cilia with long appendages. Male infl. comant, the bracts like the leaves.

HAB.—On mortar of walls and stony ground, not uncommon. Fr. 5—6.

Tyfry, N. Wales (*Wilson* 1856)!! Oxford, Bangor and Aber (*Boswell* 1863)!! Moffat (*Howie* 1863)!! Beddgelert (*Holmes* 1876)!! Tremode, I. of Man (*Holt* 1884)!! Warminster, Somerset (*Binstead* 1887)!! Castlethorpe, Bucks. (*H. N. Dixon* 1890)!!

Intermediate between *B. erythrocarpon* and *B. bicolor*, resembling the former in the shape of the capsule, and the latter in the leaves, the cells of which are denser than in either, the obtuse lid is also a marked feature.

22. **BRYUM RUBENS** Mitten.

Dioicous; leaves ovate acuminate, narrowly limbate, faintly serrate at apex, nerve excurrent. Caps. as in *B. erythrocarpon*. (T. LXXIII, A.)

SYN.—*Bryum radiculosum* BRID. Sp. musc. III, 18 (1817), Mant. 118 (1819), Bry. univ. i, 655 (1826) ?

Bryum rubens MITT. in Lond. Journ. of Bot. 1856, p. 232. Journ. Linn. Soc. i, Suppl. 69 (1859).

Bryum erythrocarpon β. *sylvaticum* HAMPE Exsicc. n. 201.

Bryum erythrocarpon Var. *limbatum* BERTHOUMIEU Rev. bryol. 1883, p. 67.

Dioicous; stems short, in rather loose tufts, rufous at base. Leaves dull yellowish green, ovato-elliptic, acuminate, faintly serrate at apex or entire, margin plane with a narrow yellowish limb of 3—5 rows of extremely narrow linear cells, the rest being firm, hexagonal with thin walls, the basal hexagono-rectangular; nerve reddish, excurrent in an apiculus; perich. bracts smaller than the leaves, narrower, with a more distinct border. Seta red, variable in length; caps. cernuous, clavate-oblong, rusty red, lid large, brighter red, shining, shortly conical with an acute apiculus; teeth of peristome small, attenuated in the upper half. Male plants short, the infl. terminal.

HAB.—On the ground, not common.

Hurstpierpoint and Maresfield, Sussex (Mitten 1849) !!

This moss appears to be specifically distinct by its bordered leaves, though coming near to *B. erythrocarpon*, in fact *B. bicolor*, *erythrocarpon*, *rubens*, *murale* and *marginatum* form a very closely allied group, which may be connected by intermediate forms. The present species may belong to *B. radiculosum* of Bridel, but it must remain doubtful as he does not describe the border to the leaf. The leaf-cells are wider than in *B. erythrocarpon*, and according to Mr. Mitten it is found in central Europe, N. Asia and N. America.

23. **BRYUM MILDEI** Juratz.

Dioicous; in dense pulvinate tufts. Leaves imbricated, erecto-patent, ovato-lanc. acute, entire, revolute at margin, nerve excurrent in an apiculus. Caps. pendulous, obovate. (T. LXXIII, B.)

SYN. *Bryum apiculatum* (non SCHWAEG.) WILS. Bry. br. 245, t. 50 (1855).

Bryum Mildeanum JURATZ. Verh. z.-b. Gesells. Wien 1862, p. 967, et in Bot. Zeit. 1864, III, n. 5. Laubm. oester.-ung. 275 (1882). MILDE Bry. siles. 216 (1869). DE NOT. Epilogo 402 (1869). SCHIIMP. Synops. 2 ed. 446 (1876). BOUL. Musc. de Fr. i, 254 (1884). HUSN. Musc. gall. 246, t. 66 (1889).

Dioicous; densely pulvinato-cæspitose, yellow-green above with a silky gloss, dark brown at base with some rufous radicles. Stems $\frac{1}{2}$ —1 in. high, dense leaved, with slender branches. Leaves erect and imbricated when dry, erecto-patent when moist, sometimes red at base, elliptic or ovato-lanc., gradually pointed, carinate-concave, margin revolute to apex, entire, or with a few irregular teeth at point, nerve rufescent at base, strong, excurrent in a short point, areolation dense, narrowly hexagonal above, narrower at margin, quadrato-hexagonal at base. Caps. on a rufous-purple seta, inclined or pendulous, obovate-oblong narrowed into a slightly incurved neck, rufescent, finally castaneous, scarce contracted below the mouth when dry; lid convex-conic, mammillar, shortly apiculate, rufous, shining. Teeth of per. lanceolate yellow, processes of endostome perforated, with 2—3 cilia.

HAB.—Wet rocks and by waterfalls. Fr. 7—8.

Holwick Scarr and Maizebeck, Teesdale (*Spruce* 1843)!! Slemish mountain, Antrim, Ireland (*Moore*)! Kilrock Quarry, Howth (*Orr*). Baie de Gouffe, Guernsey (*Cardot* 1885)!! all sterile.

This moss in habit and colour closely resemble *B. cæspiticium*, and it also comes near *B. Funckii* SCHWAEG. The Teesdale specimens are densely tufted and have shorter leaves than the type, while Moore's specimens are laxer with a laxer areolation, probably due to a greater amount of moisture at its place of growth.

24. **BRYUM MUEHLENBECKII** Br. Sch.

Dioicous; in loose olivaceous-green tufts, dichotomously branched. Leaves erecto-patent, imbricated, elliptic-oblong rather obtuse, incurved at point, revolute at margin, nerve vanishing. Caps. pendulous, oblong, ferruginous. (T. LXXIII, C.)

SYN.—*Bryum alpinum* Var. *brevifolium* MYRIN Cor. Fl. ups. 68 (1833).

Bryum Raui AUSTIN in COULT. Bot. Gaz. ii, 110.

Dioicous; in laxly cohering olivaceous-green opake tufts. Stems repeatedly dichotomous, fastigiate, radiculose at base, flaccid. Leaves densely crowded, imbricated, erect, lower ovate, upper elliptic-oblong, parabolically pointed, with the apex obtuse incurved and somewhat cucullate, all carinate-concave, entire, margin revolute, nerve rufous, vanishing at apex, cells much laxer than in *B. alpinum*. Seta red, erect,

hooked at apex; caps. from a slender neck, elongato-pyriform, rufescent or fuscous, not constricted at mouth; lid hemispherical, mucronate, glossy, teeth of per. yellowish, lanceolate, processes of end, lanceolate, attenuate, gaping at the keel, cilia in pairs, appendiculate.

HAB.—Wet mountain rocks; rare. Fr. 7—8.

Devonshire (Herb. Hooker). Ben Nevis (Stirton 1866)! Sleddale Forest, Westmoreland, on a wet rock (Binstead 1886)!!

Closely resembling *B. alpinum*, but differing in the dull olivaceous colour, and broader, more concave and more obtuse leaves incurved at point. All the British specimens are sterile.

25. BRYUM ALPINUM Huds.

Dioicous; in dense glossy purple tufts, the stems but little branched. Leaves imbricated, straight, lanceolate, recurved at margin, nerve reaching point or excurrent. Caps. pendulous, oblong-pyriform, dark red, constricted below mouth. (T. LXXIII, D.)

Bryum alpinum Var. *gemmiparum* HUSN. *Musc. gall.* 247 (1889).

Dioicous; in dense light brownish-green tufts, matted at base with rufous tomentum and coated with earth. Young shoots green, 1—3 given off below the apex of stem, often with bulbiform gemmæ in axils of upper leaves. Leaves dense, imbricated when dry, erecto-patent when moist, lower ovate, acuminate, upper ovato-elliptic, very concave, entire, narrowed into a bluntnish point, margin recurved in the lower half, nerve yellowish, ending in the apex or just below it; cells chlorophyllose, rhomboid-hexagonal, rather laxer at base, quadrate at angles, gradually longer and narrower at margin so as almost to form a limb. Caps. ovato- or oblongo-pyriform, reddish brown, inclined or pendulous, lid convex shortly apiculate, teeth yellowish, processes pale, gaping. Male plants intermixed, innermost bracts nerveless.

HAB.—Wet rocks in limestone districts of South Europe. Fr. 4—5.

Rocks by R. Usk near Senny bridge, Monmouth (*Boswell and Ley* 1883)!! and in R. Grwyne, Brecon (*Rev. A. Ley* 1890)!!

I find this is nearer *B. Muehlenbeckii* than *B. alpinum* to which I had referred it. It differs in the young shoots being green, the leaves thinner, soft,

not decurrent, with blunt points, thinner nerve and long narrow marginal cells. The fruit is very rare and our plants are quite sterile; it is essentially a plant of the Mediterranean region.

27. **BRYUM PALLENS** *Swartz.*

Dioicous; in brownish green or reddish tufts. Leaves lax, ovate-acuminate decurrent, narrowly limbate, nerve slightly excurrent. Caps. long-necked pyriform, slightly incurved, pale brown. (T. LXXIII, E.)

Bryum origanum Bosw. in Naturalist 1879 p. 33. HOBK. Synops. 2 ed. 166 (1884).

Dioicous; in soft lax or dense tufts, dingy olive-green, wine-coloured or rosy purple, dark brown at base. Stems short, with a few innovations at summit. Leaves erecto-patent, lower remote ovato-lanc., decurrent, upper crowded, oblong and elongate, acuminate, all with a narrow brownish limb, of 2—3 rows of incrassate cells; margin entire, plane above, revolute in lower half; cells lax, rhombo-hexagonal, at base hexagono-rectangular, nerve strong, reddish, ending at apex or shortly excurrent. Caps. on a long brownish-red seta, horizontal or inclined, cinereous or yellowish, castaneous when old, pyriform with a long somewhat incurved neck, scarcely contracted below the mouth; lid rather large, apiculate, yellow shining. Peristome yellow, densely articulated, endostome paler, when dry projecting between the teeth. Male plant more slender, infl. gemmiform, the bracts lanceolate, divergent.

HAB.—Rocks and stones by streams and wet ground. Fr. 6.

Var. $\beta.$ *speciosum* (*Voit*) Schimp.

Taller ; caps. larger, inclined, on a longer seta ; lid smaller.

Bryum subobliquum LINDGR. Bot. Not. 1842, p. 18.

Dioicous; in dense olivaceous green tufts, interwoven with brown tomentum. Stems erect, 2—6 in. high, red, rigid, slightly branched. Leaves accrescent upward, comant, erecto-patent, decurrent at base, oblong-lanc., gradually apiculate, slightly serrulate at point, nerve strong, rufous, prolonged into the point; margin reflexed, with a yellow limb of 3—5 rows of narrow cells, upper cells incrassate, rhombo-hexagonal, basal red, rectangular. Capsule on a long purple seta, pendulous, ferruginous, elongate-obconic, often slightly curved upward and subventricose beneath, constricted below the mouth when dry; lid of the same colour, mamillar, glossy; peristome pale red. Male infl. subdiscoid-gemmiform, the bracts broadly ovato-cordate, acuminate, nerved.

HAB.—Moorland bogs and wet rocks by streams, not uncommon.
Fr. 6—7.

Var. β . *compactum* *Bv. Sch. Bry. eur. l. c.*

Stems short, compactly tufted. Capsule shorter, obovate, with a more pointed lid.

HAB.—On the higher mountains. Southport (*Whitehead 1863*)!

This moss often grows in large patches, and when loaded with fruit has a very beautiful appearance. On moorland banks where water is always trickling down, it may generally be found in perfection, and is a more robust plant than *B. bimum*, from which it is best distinguished by the dioicous inflorescence and more or less ventricose capsule.

31. **BRYUM NEODAMENSE** *Itzigs.*

Dioicous; in lax brownish green tufts. Leaves lax, remote, upper obovate-oblong, somewhat cucullate, limbate, nerved to apex. Caps. pendulous, obovate, constricted below mouth. (T. LXXIV, C.)

SYN.—*Bryum neodamense* ITZIGSOHN in Flora 1841, I, p. 360. C. MUELL. Synops. i, 258 (1848). HOBK. Synops. 112 (1873). SCHIMP. Synops. 2 ed. 460 (1876). JURATZ. Laubm. oest.-ung. 290 (1882). BOUL. Bryum pseudotriquetrum δ *cavifolium* SCHIMP. Coroll. 76 (1856), Synops. 376 (1860). MILDE Bry. siles. 219 (1869).

Bryum cavifolium WILS. MSS.

Dioicous; in tall lax brownish green tufts, interwoven with brown radicles. Stems slender, lax-leaved, red, dense leaved at apex. Lower leaves small, distant, ovate, obtuse, the nerve ending below apex, upper comant, larger, patent, decurrent, obovate and elliptic-oblong, very

concave, twisted when dry, nerved nearly to apex, or in the uppermost excurrent in a point; margin erect entire, limbate with 3—6 rows of narrow yellowish cells, upper leaf cells rhombo-hexagonal, basal rectangular. Caps. on a long seta, pendulous, brown, obovato-obconic, the neck shorter than sporangium, constricted below the mouth when dry, lid shortly apiculate. Male plant as in *B. ventricosum*.

HAB.—Wet heaths near the sea; rare. Fr. 7.

South sands at Southport (*Dr. Wood* 1859)!! Sands of Barrie, Dundee (*Rev. J. Fergusson* 1871)!

This moss, if not a very elegant one, has quite a distinct habit not much like that of *B. ventricosum*, and may easily be recognised by its broad obtuse entire leaves. The fruit is very rare and has only once been found in England.

32. **BRYUM CYCLOPHYLLUM** (*Schwaeg.*) *Br. Sch.*

Dioicous; in soft bright green tufts. Leaves distant, broadly obovate, entire, concave, obtuse, nerve vanishing below apex. Caps. pendulous shortly pyriform, lid large, yellow. (T. LXXV, D.)

SYN.—*Mnium cyclophyllum* SCHWAEG. Suppl. II, P. II, 160, t. 194 (1827). HUEBEN. Musc. germ. 422 (1833).

Dioicous; in soft lax bright green tufts, blackish at base. Stems short and slender with few branches. Cauline leaves remote, narrowed at base, broadly obovate, comal larger, few, broadly oblong, all concave, obtuse, quite entire, curled when dry, nerve vanishing below apex, cells lax, soft, rhombic-hexagonal, indistinctly limbate by 1—2 rows of long narrow ones. Caps. pendulous, shortly pyriform, leptodermous, pale ferruginous, wide-mouthed, strongly contracted below it when dry; lid large, mamillar, yellow, glossy; teeth ferruginous at base, incurved when dry. Male plant in distinct tufts, the infl. 3—4 gemmiform, among the comal leaves.

HAB.—Mud of dried up pools on peat-moors; rare. Fr. 6. Gathered in the Grampians by Mr. Grant, of Lossiemouth. (*Scottish Naturalist*, iv, p. 61.)

The only record I have of this as a British moss is that by Mr. Fergusson in the journal mentioned, and with so distinct a plant it is not likely there

could be any mistake. The figures are from Swedish specimens and will enable our young collectors to identify it, if they should be fortunate enough to meet with it.

33. BRYUM CAPILLARE L.

Dioicous; in dense tufts reddish at base. Leaves spirally twisted when dry, obovate or spatulate, with long hair-points, limbate with 1—4 rows of yellow cells, entire; nerve vanishing at point. Caps. clavate or cylindric. (T. LXXIV, D.)

HAB.—Woolsonbury hill, Sussex; ster. (*Mitten* 1849)!

Var. δ . *flaccidum* Schimp.

Stem slender, with many slender branches, often with axillary chlorophyllose brood-filaments. Leaves laxer, soft, patulous, more distant, not spirally twisted, narrowly limbate, undulate, serrate at point.

SYN.—Bry. eur. fasc. 6—9, p. 61, t. 29.

B. capillare Var. *angustatum* BOULAY Musc. de l'Est p. 396 (1872). ~

HAB.—Crow road, Campsie (*Hunt* 1866)! Wall at Malham, Yorks. (*Binstead* 1885)!! Newtimber, Sussex (*Davies*).

Var. ϵ . *Ferchelii* (*Funck*) Br. Sch.

Compactly tufted, dull green or brownish. Leaves appressed, small, concave, obovate-acuminate, suddenly narrowed into a twisted point.

SYN.—*Bryum Ferchelii* FUNCK m.s. BRID. Bry. univ. i, 847.

B. capillare Var. *Ferchelii* Bry. eur.

HAB.—Old wall at Killin (*Hunt* 1866)!!

Var. ζ . *obconicum* (*Hornschr.* in lit.) Hueben.

Densely tufted; leaves appressed or but little twisted when dry, ovate, acuminate, the comal erect and incurved. Capsule with a longer neck.

SYN.—*Bryum obconicum* HORNSCH. in lit. Bry. eur. WILS. Bry. brit.

B. capillare Var. *obconicum* HUEBEN. Musc. germ. 442. HUSN. Musc. gall. 241.

HAB.—Walls and sandstone rocks.

Barnard Castle (*Spruce* 1843). Hill cliff quarry (*Wilson* 1860)!! Thirsk (*Nowell* 1854)! Slate rocks at Bangor (*Hunt* 1854)!! Rossit and Gresford (*Hunt* 1860)! Greta bridge (*Borrer*). Mucruss, Killarney (*Hunt* 1867)!! Dailly, Ayr (*Shaw* 1865). Shaughbridge, Devon (*Holmes*)!! Levens (*Barnes*)!! Luxulyan, Cornwall (*Holmes* 1884).

Like all mosses of wide distribution *B. capillare* varies much both in the fruit and leaves, and after examining a large number of specimens of *B. obconicum*, I feel constrained to rank it among the varieties, as none of its characters appear to me weighty enough to be of specific value. Non-twisted leaves occur in several forms of *B. capillare*, and the capsular neck varies considerably in length, as does also the acumination of the leaf point, but the cell-structure of the leaves is identical. Of course if we are to adopt the modern idea of *subspecies*, as well as varieties, then *obconicum* must rank among the former.

34. *BRYUM DONII* *Grev.*

Dioicous; resembling *B. capillare*. Leaves spreading, slightly crisped when dry, ovate-oblong, subserrate at apex, with a narrow thickened border, nerve scarcely excurrent. Caps. conico-clavate. (T. LXXV, A.)

SYN.—*Bryum corsicum* WALK. ARN. MSS.

Bryum capillare ♂. *corsicum* BRID. Bry. univ. i, 849 (1827).

Bryum Donianum GREV. in Trans. Linn. Soc. xv, 345, t. 3, f. 6 (1828). WILS. Bry. br. 241, t. 49 (1855). SCHIMP. Synop. 373 (1860), 2 ed. 454. BERK. Handb. br. m. 196 (1863). DE NOT. Epil. 391 (1869). Bryum Muelleri SPRUCE Musc. Pyr. 138, et Ann. mag. nat. hist. 1849.

Dioicous; resembling *B. capillare*, but shorter and in smaller tufts. Upper leaves crowded in a coma, erecto-patent, somewhat twisted when dry, subpathulate-oblong and elongate, limb yellowish, narrow and incrassate of 2—3 strata of narrow pachydermous cells confluent with the apical mucro, distantly serrate at point; nerve strong, excurrent in a solid fuscous point; cells denser, more solid. Caps. inclined, rather large, oblongo-obconic, rufous-brown, lid mamillar, castaneous, very glossy. Male infl. gemmiform, in the coma.

HAB.—Gravelly banks and rocks; not common. Fr. 5—6.

Near Winchelsea, Sussex (*Jenner* 1844)! Winwick stone quarry near Warrington and Conway (*Wilson*). Damp sand-bank near Hurstpierpoint (*Mitten*). Penzance (*Curnow* 1869)!! Lancing and Betchworth (*Davies* 1857)!! Dadnor, near Ross (*Rcv. A. Ley* 1890)! Torquay and Anglesey.

This fine moss bears much resemblance to *B. capillare*, but the leaves have only short points with the nerve just excurrent, and a much thicker limb. It is most frequent in the Mediterranean region and Canary Islands.

35. BRYUM PROVINCIALE *Philib.*

Polyoicous; stem branched, the innovations with the comal leaves suddenly larger and crowded, ovate-oblong concave, serrulate in upper part, the nerve excurrent. Capsule pendulous, obconic-pyriform. (T. LXXV, B.)

SYN.—*Bryum Billardieri* (non SCHWAEGR.) BR. SCH. Bry. eur. fasc. 6—9, p. 58, t. 26 (1839). WILS. Bry. brit. 242, t. 50 (1855). HOBK. Syn. br. m. 118 (1873).

B. Canariense Var. *provinciale* HUSN. Musc. gall. 239 (1889).

Polyoicous; the same plant often bearing male, female and synoicous infl. Laxly cæspitose, bright green above, fuscous at base with ferruginous tomentum, the innovations single or in pairs. Lower leaves remote, small, ovato-lanc., shortly cuspidate, upper suddenly larger, crowded in a many leaved rosette, not limbate, the outer concave obovate, shortly acuminate, nerve strong rufous excurrent in a short point, margin narrowly recurved in lower half, plane and minutely serrate above; the median lineal-oblong acuminate, rather more cuspidate; the inner narrower, the margin to apex more broadly reflexed; cells rhombic-hexagonal above, rectangular and red at base. Perich. bracts smaller lanc., longly cuspidate, margin subrevolute. Capsule on a rufous seta, pendulous, longly obconic, rufous-orange, not contracted below the mouth; lid convex-conic, pointed, reddish-brown, annulus broad; peristome large, the teeth yellow below, hyaline above, processes widely gaping.

HAB.—Calcareous hills in S. of England; rare. Fr. 5.

Old ant hills on Woolsonbury hill, Sussex (*Mitten*)!! Ightham, Kent c. fr. (*Holmes*). Worthing. Wookey, near Wells, Somerset c. fr. (*Binstead* 1887)!! Lord's wood, Great Doward hill, Hereford c. fr. (*Rev. A. Ley* 1874)!

Another moss allied to *B. capillare* but with non-limbate leaves, and with a different habit, the stem being interrupted by the leaves clustering into rosettes. *B. Canariense* BRID. has a similar habit but is dioicous, the leaves with a denser areolation and more minutely serrulate. *B. Billardieri* SCHWAEG. is Australian.

36. **BRYUM BARBATUM** Wils.

Dioicous; densely cæspitose, soft, fastigiate branched. Leaves ovate, pointed, running out into a recurved apiculus, nerve reaching point or excurrent, margin erect entire, not limbate, cells hexagono-rhombic. (T. LXXV, E.)

SYN.—*Bryum barbatum* WILS. MSS. HUNT in Mem. Lit. Phil. Soc. Manch. 3 ser. iii, 238 (1866). HOBK. Syn. br. m. 114 (1873).

Bryum Stirtoni SCHIMP. Synops. 2 ed. 470 (1876). LIMPR. in RABENH. Deutsch. kr. flora, Laubm. ii, 431 (1893).

Dioicous; densely cæspitose, soft, light green above, pale brown below with rufous tomentum. Stems $1\frac{1}{2}$ in. high, red, slender, fastigiate branched. Lower leaves smaller remote patent, ovate, shortly pointed, submuticous, nerve vanishing below or in the apex, upper rather larger with a recurved apiculus, nerve yellowish-green, ending at the point or excurrent as a short hair; both concave the margin erect, entire not limbate, cells chlorophyllose, shortly hexagono-rhombic, larger and longer at base, in the perich. bracts longer, narrower, and red at base, enclosing a few archegonia and paraphyses.

HAB.—On the ground near summit of Ben Ledi. (Stirton & McKinlay 1864) !!

This moss has unfortunately never been found with fruit, but in habit it resembles some forms of *B. pallens*, though perhaps coming nearest to *B. capillare* in form and structure of leaf. It does not appear to have been found again since its first discovery, nor to have been met with in any other locality.

37. **BRYUM PROLIFERUM** (L.) Sibth.

Dioicous; laxly cæspitose. Cauline leaves minute, squamiform, comal large, crowded in a rosette, spathulate, apiculate, serrated, nerved to apex. Capsules aggregated, oblong pendulous slightly incurved. (T. LXXV, C.)

BREUTELIA SCHIMP.

Breutelia chrysocoma (Dicks.) Lindb.

CATOSCOPIUM BRID.

Catoscopium nigritum (Hedw.) Brid.

Fam. 16. BARTRAMIACEÆ.

Perennial mosses growing in tomentose cushioned tufts, innovating below the inflorescence and finally becoming dichotomous. Leaves in 5—8 rows, ovato-lanceolate or subulate, serrated at margin and often at back of nerve, mamilloso-papillose on both sides, very rarely smooth, the papilla being near the transverse wall at end of cell, the upper cells small rectangular or quadrate, the basal smooth, hexagono-rectangular. Calyptra small, cucullate, very fugacious. Capsule more or less spherical, without a neck, cernuous or rarely erect, with an oblique mouth, when dry pressed in at base, striated and furrowed, rarely smooth. Annulus none. Lid minute, muticous. Peristome rarely none or simple, teeth 16, inserted below the mouth of capsule, often between the lamellæ in the upper half, having on the inner side, central thickened deposits; endostome shorter, carinate-plicate, the processes cleft into two diverging legs, cilia none or ill-developed. Male infl. terminal discoid, rarely gemmaceous.—Inhabiting the earth, rocks or bogs.

This family of over 200 species is one of the most beautiful among mosses, especially in the larger forms, and is marked by the globose fruits which before ripening are often covered with a glaucous bloom. It is widely distributed, but about half the species are natives of S. America, and we have 22 in Europe.

Sect. 1. BARTRAMIEÆ. Capsule large, striato-sulcate, teeth lanceolate; leaf-cells papillose.

1. CONOSTOMUM Swartz.

Schrad. neu Journ. Bot. I, P. III, 26 (1806).

Plants erect, straight, densely crowded in small fastigiate tufts, tomentoso-radiculose. Leaves in 5 rows, imbricated, lanceolate carinate, with the areolation of *Bartramia*. Calyptra cucullate, long persistent. Capsule elevated on a tall seta, cernuous, turgidly obovate, striate; lid minute with a short beak. Peristome simple of 16 teeth, long lineal-lanceolate, connivent into a cone and bound together at apex. —Der. *κων* a cone, *στόμα* mouth.

A genus closely allied to *Bartramia* and depending chiefly on the elegant dome-like arrangement of the teeth of peristome. Four more species are recorded, natives of S. America and Australia.

CONOSTOMUM BOREALE Swartz.

Dioicous; compactly tufted, slender, fragile. Leaves in 5 rows, narrow lanc., cuspidate, serrate at apex. Caps. obovate, striate, deeply furrowed. (T. LXXVI, A.)

Bartramia conostoma BR. SCH. Bry. eur. fasc. 12, p. 16, t. 7 (1842). RABEN. D. kr. fl. ii, S. 3, 191 (1848).

Conostomum tetragonum LINDB. Oefv. K. Vet.-Ak. Foerh. 1863, p. 8.

Dioicous; compactly tufted, glaucous green above, brown at base; plants slender, fragile, fastigiate. Leaves densely crowded in 5 rows, erect, rigid, the lower lanc., gradually becoming longer upwards, narrowly lanc., serrate at apex, acute, carinate; nerve reaching apex, in the upper leaves excurrent in a long point and slightly serrate at back, leaf-cells rectangular; perich. bracts larger, thinner with a thin nerve. Seta pale red, caps. turgidly obovate, pale brown, deeply sulcate; peristome inserted far below the mouth, teeth 16, purple, linear-lanc., distant from each other at base, connate at apex. Male infl. round, bracts from a broad base, concave, lanceolate, innermost shorter, laxly areolate.

HAB.—Damp peaty places on the higher Scotch mountains. Ben Lomond, Ben Lawers, Craig Chailleach, &c. Fr. 7—8.

Characterized by the peristome, the teeth of which arch gracefully inward and are united together by their points. As the original name *tetragonum* expresses an error, I have maintained the later one of Swartz.

2. BARTRAMIA *Hedw.*

Descr. Musc. frond. ii, 111 (1789).

Stem erect dichotomous branched, the cuticle of small cells. Leaves in 8 rows, opake, lanceolate or lineal-subulate, papillose; cells small rectangular. Capsule globose, striate, sulcate; peristome rarely none or simple, teeth 16, endostome a narrow basal membrane with 16 carinate processes shorter than the teeth, finally separating into two divergent legs, cilia rarely present. Inhabiting the ground or rocks.—Der. after John Bartram, of Pennsylvania, who sent mosses to Dillenius.

CLAVIS TO THE SPECIES.

Leaves smooth on both sides.	<i>Oederi.</i>
— papillose.	
Leaves not sheathing at base.	
Leaves rigid, capsule regular, erect.	<i>stricta.</i>
— crimped, capsule irregular, inclined.	<i>pomiformis.</i>
— sheathing at base.	
Seta straight. Leaves plane at margin.	<i>ithyphylla.</i>
— short and arched. Leaves revolute at margin.	<i>norvegica.</i>

Sect. I. OREADELLA *C. Muell.* Stems fastigiate branched. Leaves complicate-carinate, revolute at margin, smooth.

I. BARTRAMIA OEDERI (*Gunn.*) *Sw.*

Synoicous; in large dull green tufts. Leaves lanceolate, smooth, patenti-recurved, revolute at margin, carinate, serrate at apex. Capsule small globose. (T. LXXVI, B.)

Synoicous; in dense bluish-green or yellowish-green tufts with ferruginous tomentum, the branches fastigiate. Leaves erecto-patent rigid, straight when dry, from a white dilated sheathing base suddenly lineal-subulate, the margin flat and sharply serrulate, nerve broad,

occupying almost the whole subula, cells at base, linear, above rectangular. Caps. inclined, spherical, striate, pale brown, when dry oblong incurved, deeply sulcate, lid conical, muticous; teeth rufo-fuscous, endostome orange, half length of teeth.

HAB.—On the ground and clefts of rocks in the mountains. Common. Fr. 6. Resembling a small state of *B. pomiformis*, but readily distinguished by the straight subulate leaves with sheathing white bases.

3. PHILONOTIS *Brid.*

Bry. univ. ii, 15 (1827).

Plants short and decumbent or tall and erect, the fertile apex with verticillate or fascicled innovations, the rest dichotomous with binate innovations, and shoots placed spirally below the male infl., densely tomentose, the cuticular cells of stem large and vesicular. Leaves uniform or biform, one or both cell-angles with a papilla. Caps. cernuous globose, striate; cilia of endostome distinct binate. Growing in bogs or wet places.—Der. φιλεω to love, νοτια moisture.

A genus of some 80 species, in the larger forms possessing a very natural habit, and some so closely allied that considerable difficulty is experienced in drawing up their distinctive characters. Most of them require a permanent supply of moisture, and hence they thrive best in moorland bogs or where trickling springs permeate the surface.

CLAVIS TO THE SPECIES.

Autoicous.		
Very small, gymnostomous.		<i>Wilsoni.</i>
Short, fasciculate-branched, peristomate.		<i>rigida.</i>
Dioicous.		
Leaves densely imbricated.		
Bracts of male infl. acute, nerved to point.		
Leaves falcato-secund, laxly areolate.		<i>calcarea.</i>
— secund, densely areolate.		<i>cæspitosa.</i>
— obtuse, nerve vanishing.		
Upper leaves imbricated, erecto-patent.		<i>fontana.</i>
— in spiral rows, appressed.		<i>seriata.</i>
— distant, erecto-appressed, decurrent.		<i>adpressa.</i>

Sect. I. PHILONOTULA C. Muell. Plants dwarf, procumbent, fasciculate, and irregularly branched, with erect or secund leaves. Synoicous or autoicous, ♂ gemmaceous.

I. PHILONOTIS WILSONI (*Br. Sch.*)

Synoicous; minute, fasciculate branched. Leaves ovate-acuminate, nerved to apex. Caps. subpyriform, smooth, gymnostomous. (T. LXXVII, B.)

Bartramidula cernua LINDB. Oefv. Vet.-Ak. Foerh. 1863, No. 7.

Synoicous; small slender procumbent at base, in little pale green lax tufts. Leaves erecto-patent or subsecund, lanceolate, acute smooth, margin flat, denticulate above; cells lax, elongate rectangular above, wider at base; nerve ending below the point. Caps. 2—5 in one perichaetium, very soft, globoso-pyriform with a short neck, on an arcuate seta, cernuous, pale brown, not striate, wrinkled when dry; lid very small plano-convex; peristome none.

HAB.—Heathy ground on mountains, rare. Fr. 10.

Connor hill, Dingle (*Wilson* 1829)! Knockavohila, Kenmare (*Taylor*). Cwm Bychan, Harlech (*Rev. T. Salwey* 1841)! Glen Dole, Clova (*Croall*).

Except in the stations quoted, this pretty little moss has only been recorded from the island of Fernando Po (*Mann*); its delicate capsule is usually tinged with pink when growing, but this is lost in drying. About 30 species of this group are known.

2. PHILONOTIS RIGIDA Brid.

Autoicous; densely, cæspitose, glossy. Leaves erect, straight, lanceolate, serrulate with excurrent nerve. Caps. obliquely cernuous, striate. (T. LXXVII, C.)

SYN.—*Philonotis rigida* BRID. Bry. univ. ii, 17 (1827). SCHIMP. Synops. 424 (1860), 2 ed. 517. DE NOT. Epilogo 259 (1869). JURATZ. Laubm. oester.-ung. 331 (1882). BOUL. Musc. de Fr. 217 (1884). Autoicous; in small tufts, glossy brownish green above and dense reddish tomentum at base. Stem short, vaguely and fasciculate branched below the inflorescence, fragile. Leaves crowded erecto-patent, appressed when dry, rigid, lanceolate, shortly aristate with the stout excurrent nerve, margin sharply serrated, slightly reflexed; cells papillose at upper end, narrowly rectangular above, laxer and wider at base. Perich. bracts few, shorter than vaginula, from a

broadly ovate base, lanceolate-subulate. Caps. on a long red seta, large globose with a narrow mouth, striate, pale brown, lid convex apiculate; teeth of peristome shorter dark purple, incurved when dry, with interlamellar thickenings in the upper half, endostome orange, papillose. Male infl. near the female, gemmiform, bracts ovato-lanc.

HAB.—Wet rocks and sandy banks; rare. Fr. 6

Bantry (*Miss Hutchins*). Maghanabo Glen, Dingle (*Wilson* 1829). Dunkerron and Killarney (*Taylor*) !! Mousehole cave, Penzance (*Curnow*). Beddgelert (*Hunt*) !! Friog, Monmouth (*Percival* 1877). Arklow (*Moore*) ! Sulby Glen, Kirkmichael, Laxey and near Douglas, Isle of Man (*Holt* 1886) !! Porthmeor cove, W. Cornwall (*Marquand* 1880).

This species is allied to *P. marchica* (WILLD.) BRID. A moss which has been reported more than once as British, and ought to be found here, as it is met with throughout Europe, but hitherto it has not been identified among native specimens. *P. marchica* is dioicous, the leaves with plane margins, and acute pointed perigonal bracts; otherwise it resembles a slender state of *P. fontana* which has generally been mistaken for it.

Sect. 2. EUPHILONTIS. Plants more robust, erect; cuticle of stem formed of large leptodermous hyaline cells. Dioicous, ♂ discoid.

3. *PHILONOTIS CÆSPITOSA* Wils.

Dioicous; densely tufted, short and slender. Leaves biform, the appressed ovate with plane margins, the secund subfalcate, lanceolate, all non-plicate. Capsule horizontal. (T. LXXVII, E.)

SYN.—*Philonotis cæspitosa* WILS. MSS. MILDE Bry. siles. 241 (1869). HOBK. Synops. 130 (1873). HUSN. Musc. gall. 269, t. 75 (1890). LIMPR. in RABENH. D. kr. fl. Laubm. ii, 570 (1893).

Philonotis fontana β. *cæspitosa* LIMPR. Krypt. fl. v. Schl. 116 (1875). HOBK. Synops. 2 ed. 150 (1884). BOUL. Musc. de Fr. 216 (1884).

Dioicous; in soft dense dull-green tufts, stems slender, 1—2 in. high, united by blackish-brown tomentum, the branches falcate at point. Leaves biform, the appressed leaves ovate, concave, pointed, with plane margins, the secund leaves subfalcate, lanceolate, with long points, all without plaits and the margins with distant small teeth; nerve thin, shortly excurrent; upper cells thick-walled, narrow, with a papilla at the lower angle, the basal oval and rectangular, smooth. Capsule resembling that of *P. fontana*. Male plants shorter, the bracts erecto-patent, very broadly ovate, acutely pointed, nerved to the apex.

HAB.—Swamps and boggy heaths, rare and sterile. Fr. 6.

Walton Swamps, Cheshire (*Wilson* 1860) !! Harts hill, Henfield, Grendon, Curdworth, footways near Hockley and Studley all in Warwickshire (*Bagnall*).

Resembling *P. marchica* in aspect and not found with fruit in this country. A section of the stem is not unlike that of *Sphagnum subsecundum*.

4. **PHILONOTIS FONTANA** (*L.*) *Brid.*

Dioicous; in dense glaucescent or yellowish green tufts. Leaves biform, those of male shoot appressed, ovate acute, the rest erecto-patent or subsecund, ovato-lanc., acute, 2—3 plicate at base, nerve excurrent, denticulate with pairs of mamillæ. Bracts of male infl. broad obtuse, the nerve vanishing. (T. LXXVIII, B.)

Didymodon mollis SCHIMP. Syn. 2 ed. 167 (1876).

Dioicous; in wide dense yellowish or glaucous-green tufts, interwoven with ferruginous tomentum. Stem tall nearly simple or giving off several long branches below the infl. Leaves biform, the upper of the male shoot small ovate, appressed, bluntly acuminate, nerved to apex; those of the main branches erecto-patent or somewhat secund, ovato-lanc., acute or aristate with the excurrent nerve, the base with 1—2 plaits on each side, the margin revolute in the lower half, bluntly toothed by pairs of mamillæ; cells elongated, with a papilla at the

lower angle. Seta slender purple. Caps. inclined, ovato-globose, pachydermous, when dry curved and sulcate; lid small conic, teeth of peristome purple, finely papillose, the upper third with hemispherical thickenings between the lamellæ. Male infl. broadly discoid, inner bracts from an erect yellow base, shortly ovato-lanceolate, obtuse serrate, the nerve broad thin, vanishing.

HAB.—About springs and gravelly moorland bogs. Fr. 6—7.

Var. β . *falcata* Brid.

Branches hooked at apex. Leaves falcato-secund lanceolate-subulate, nerve stronger, rufescens, perigonial bracts acute with excurrent nerve.

SYN.—*P. fontana* var. *falcata* BRID. Bry. univ. ii, 21. SCHIMPER, WILSON, C. MUELL., &c.

HAB.—Twll du (*Hunt* 1865) !! near Killin (*Binstead* 1885) !!

Var. γ . *capillaris* Lindb.

Tufts small, lax., the stems extremely slender $\frac{1}{2}$ in. high. Leaves distant, uniform, lanceolate-subulate, not plicate, the margin plane.

SYN.—*Philonotis capillaris* LINDB. in HEDWIGIA 1867, p. 40 et in HARTM. Skand. fl. 10 ed. ii, 46 (1871).

Var. δ . *compacta* Schimp.

In compact swollen tufts, densely tomentose; stems slender. Leaves uniform, imbricated, shortly ovato-lanc., nerve reaching apex or excurrent, margin obsoletely serrulate.

SYN.—*Phil. fontana* var. *compacta* SCHIMP. Synops. 2 ed. 520. HOBK. Syn. 2 ed. 151.

Philonotis firma FERGUS. MS.

HAB.—Clova (*Fergusson*). Ben-mac-Dhui (*Whitehead* 1876) !!

This most Protean moss is the centre of a small group of closely allied species which are difficult to discriminate and as an aid in this direction an additional character of some importance has been found in the form of the bracts in the male inflorescence. *P. pumila* has been established as a species by several authors, but apparently only for dwarf forms of *P. fontana*.

5. PHILONOTIS SERIATA Mitt.

Dioicous; resembling *P. fontana*, in rather lax tufts. Leaves of male innov. ovate, rather obtuse, the rest longer, acute, arranged in

spiral rows, appressed and with two deep plaits on each side at base. (T. LXXVIII, A.)

SYN.—*Bryum lycopodiforme* SCHLEICH. Cat. pl. Helv. 2 ed. p. 28 (1807), name only.

Bartramia fontana var. *falcata* HOOK. in Trans. Linn. Soc. ix, 317, t. 27, f. 4 (1808).

Philonotis seriata MITT. Journ. Linn. Soc. i, Suppl. 63 (1859). HUNT in Mem. Lit. Phil. Soc. Manch. v, 103 (1872). HOBK. Synops. 130 (1873). LIMPR. in RABENH. D. kr. fl. Laubm. ii, 571 (1893).

Dioicous; in stiffish yellow-green tufts with rufous tomentum, readily falling asunder, and with the habit of *P. fontana*. Leaves in spiral rows, imbricated when dry, erect or subfalcate, biform, those of the male innov. ovate, bluntish, the nerve vanishing, the rest deltoid-ovate, acutely pointed, the nerve thick, reaching apex or vanishing, all somewhat decurrent, concave, with two deep plaits at base on each side, margin revolute in lower third, bluntly toothed by single or double mamillæ; nerve very strong, rough at back, reaching to apex; cells above small and rectangular, with a mamilla at the lower and often also at the upper end, below laxer oval and longish with a central mamilla on both sides. Perich. bracts with the nerve excurrent. Caps. on a long straight seta, cernuous, striate and furrowed, lid conic obtuse, peristome rufous, endostome orange, finely papillose. Male infl. thick, bracts erecto-patent, from a very concave broad base, ovate, obtuse, finely serrate, the nerve vanishing below point.

HAB.—Bogs in alpine moorlands, rare. Fr. 7.

Ben-na-Bourd (*Gardiner* 1844). Glen Prosen hill and about springs at head of Clova (*Fergusson* 1868)!!

A very beautiful moss, the spirally imbricated arrangement of the leaves giving the branches an amentiform appearance. It is found in the Alps, Tyrol, Styria, Norway and Lapland, and has probably been overlooked as a form of *P. fontana*.

6. PHILONOTIS CALCAREA Schimp.

Dioicous; tall glaucous-green. Leaves crowded secund, ovato-lanc., gradually tapering upward, concave, margins plane. Perigonial bracts acuminate, acute, nerved to apex. (T. LXXVIII, C.)

SYN.—*Bartramia calcarea* BR. SCH. Bry. eur. Fasc. 12, p. 19, t. 10 (1842). C. MUELL. Synops. i, 475 (1849). RABENH. D. kr. fl. ii, S. 3, 193 (1848). WILS. Bry. brit. 280, t. 52 (1855). BERK. Handb. br. m. 172, t. 16 (1863). HOBK. Syn. 131 (1873).

Dioicous; more robust, in large bright green tufts, with dense dark-brown tomentum. Leaves uniform, large, crowded, secund or subfalcate, ovato-lanc., acuminate, acute, those of male shoot often incumbent, smaller with shorter points; sharply serrate at margin, revolute at base and with a faint plait near the margin, the falcate leaves revolute on one side to point; nerve thicker and more solid; cells laxer, with weaker papillæ. Perich. bracts elongated, capsule horizontal, ovato-globose, with many striæ, lid conical obtuse; teeth of peristome from a broad base, reddish-yellow, endostome orange. Perigonial bracts from an erect yellow base, spreading horizontally, longly lanc., acutely pointed, nerved to the apex, finely serrate.

HAB.—Deep moorland bogs in limestone districts. Plentiful in Teesdale where it was first found by Dr. Spruce in 1843. Fr. 7.

Very near to *P. fontana*, but the colour is so different that it has quite a distinct aspect. The laxer areolation, and acutely acuminate perigonial bracts are distinctive.

7. **PHILONOTIS ADPRESSA** *Fergus.*

Infl. unknown; plants long, slender in loose tufts, without tomentum. Leaves uniform distant, appressed, broadly ovate nerved to apex, the point bluntish and incurved. (T. LXXVIII, D.)

SYN.—*Philonotis adpressa* (non HOOK. WILS.) FERGUSSON in lit. HUNT in Mem. Lit. Phil. Soc. Manch. v. 102 (1872). HOOK. Synops. 130 (1873). LIMPR. in RABENH. D. kr. fl. Laubm. ii, 574 (1893).

P. fontana var. *adpressa* FERG. LIMPR. Krypt. fl. Schles. i, 116 (1875).

Plants slender elongated, dull or glaucous green, in loose tufts readily falling asunder and with scarcely any tomentum, and only a few short axillary shoots, the stems thin and brittle. Leaves uniform, loose and distant, appressed, broadly ovate, decurrent, very concave, the apex incurved bluntish or acute, margin revolute at base, serrate with mostly double mamillæ, nerve very strong ending just before the apex, very rough at back, with a single plait on each side at base; cells small ovoid above, oval and longish at base; in the greater part of the leaf the middle of the cell-lumen is strongly mamillose, in the upper cells the mamilla is near the lower end.

HAB.—About mountain springs, rare.

Glen Prosen and Glen Dole, Clova (Fergusson 1868). Glas Mheal, Perthshire (Hunt 1868)! Moy Laggan, Perthshire (Mrs. Farquharson 1879)! Spring under Scaur-na-Gillean, Skye (Binstead 1885)!! Ben Lawers (Dixon 1893).

A peculiar plant coming nearest to *P. seriata* in the form and direction of the leaves. *Bartramia (Philonotis) appressa* HOOK. fil. WILS. a New Zealand moss, had been previously named by them *Hypnum scabrifolium*, which may be retained for it as *Philonotis scabrifolia*.

4. BREUTELIA Schimp.

Coroll. 85 (1856).

Plants robust, coated with rufous tomentum, irregularly branched. Leaves squarrosely patent in 8 rows, with 3—4 deep plaits on each side, cells incrassate, linear. Capsule drooping, peristome as in *Bartramia*. Inhabiting the ground and wet rocks.—Der. after C. Breutel, bishop of Brüder-gemeinde.

A fine genus of about 80 species, most of them being natives of S. America. Our only species, so frequent with us, is quite rare on the Continent.

BREUTELIA CHRYSOCOMA (Dicks.) Lindb.

Dioicous; robust, in yellow-green tomentose tufts. Leaves dense squarrosely divergent, lanceolate, acuminate acute, nerve lost in the point. Caps. on a cygneous pedicel, ovato-globose. (T. LXXVIII, E.)

SYN.—*Hypnum palustre erectum, coma lutea basi nigricante* DILL. in RAY Synops. 3 ed. 83 (1724), Hist. musc. 302, t. 39, f. 36 (1741) et Herbar.

Breutelia chrysocoma LINDB. Oefv. Vet.-Akad. foerh. 1863. n. 7.

Dioicous; plants robust in large irregular tufts, coated with ferruginous tomentum, yellow-green and glossy above, stems flexuoso-erect or procumbent, irregularly branched, shorter branches patulous in whorls below the inflor., longer scattered throughout the stem. Leaves subvaginant at base, lanceolate, longly acuminate, with a thin

nerve, squarrosely divergent, with 3—4 deep plaits on each side at base, serrate at margin, nerve vanishing in the point; cells incrassate linear, at basal angles quadrato-hexagonal. Perich. bracts erect, not papillose, oblong-lanceolate. Caps. bent down on a short geniculate seta, ovato-spheric, leptodermous dingy-orange, striated and furrowed when dry; lid very small, deep red, conical, obtuse; teeth of peristome orange with hyaline points, endostome as in *Bartramia*. Male infl. thick and discoid, bracts from an erect base, divergent.

HAB.—Wet heaths and rocks in alpine moorlands and by waterfalls. Fr. 6, rare.

In fr. Lydford Falls (*Greville*)! Cromaglown (*Wilson*). Llyn Ogwen and Beddgelert. Trosachs (*Mrs. Robertson*).

This fine species is very seldom met with in fruit, but in a sterile form is frequent on subalpine moorlands where moisture is present, and in habit bears considerable resemblance to *Hylocomium triquetrum*.

Sect. 2. CATOSCOPIEÆ. Capsule very small, smooth and polished; teeth short and obtuse; leaf-cells smooth.

CATOSCOPIUM Brid.

Bryol. univ. i, 368 (1826).

Plants slender, compactly tufted, radiculose at base. Leaves erecto-patent, the cells incrassate, smooth, roundish-hexagonal. Capsule very small with a short neck, horizontal, oval-spherical, hard, black and glossy. Calyptra narrowly cucullate. Peristome of 16 lanceolate short obtuse teeth, irregular at margin. Endostome abortive. Spores large smooth. Inhabiting mountain bogs and wet rocks.—Der. κατω downward, σκοπεω to look. (T. LXXVII, D.)

The only species of the genus has some resemblance to *Disclerium* in the capsule, but in its leaf-structure finds its most fitting place in *Bartramiaceæ*.

MEESEA HEDW.

Meesea trichodes (*L.*) *Spruce.*

PALUDELLA EHRH.

Paludella squarrosa (*L.*) *Brid.*

Fam. 17. MEESEACEÆ.

Stems elongated, densely tomentose. Leaves in 3—8 rows, somewhat dense, of equal size, divergent or squarrose, entire or serrated, the cells parenchymatous above, with thick walls, lax and rectangular at base, smooth or mamillose. Capsule on a long seta, from an erect longish neck, curved clavato-pyriform, not striate, with a small oblique mouth. Peristome much shorter than endostome or of equal length, the teeth mnioid, processes of endostome 16, cilia short or rudimentary. Inhabiting wet moorlands or deep bogs.

I. MEESEA Hedw.

Fund. musc. II, 97 (1782).

Stems tomentose, densely or laxly cæspitant. Leaves in 3, 5 or 8 rows, with a solid nerve, the cells smooth, chlorophyllose, hexagono-rectangular. Caps. on a long seta, with a long narrow neck, curved pyriform, small-mouthed; calyptra narrow and cucullate, lid convex-conic; peristome of 16 short obtuse remotely articulated teeth, endostome a very short membrane with 16 processes two or three times the length of the teeth, lineal and often united at point by lateral appendages, cilia short or rudimentary. Male infl. discoid with clavate paraphyses.—Der. after David Meese, a Dutch gardener.

A small genus of 8 or 9 species, of which four are European. *M. triquetra* (L.) AONGST. should be looked for here as it is widely diffused on the continent, it is a much larger plant, having leaves in three rows and with plane margins. *Amblyodon* resembles this genus in the fruit, but the leaves are funarioid in structure.

MEESEA TRICHODES (L.) Spruce.

Autoicous and synoicous; densely tufted. Leaves in 8 rows, linear-lanceolate, obtuse, entire and revolute at margin, the cells nearly uniform. (T. LXXIX, A.)

Dioicous; in tall dense tufts, bright yellow-green above, blackish-brown at base, coated with soft brown tomentum. Leaves crowded in 5 rows, ovato-lanc., from an erect decurrent base, squarrose, strongly recurved, acutely carinate, margin recurved below, plane above, serrate at apex; nerve thin vanishing below point, cells roundish-hexagonal above, oval in the middle, elongated at base, mamillose on both sides. Perich. bracts erect, lanc., revolute at margin. Seta long, red; caps. from a short erect neck, ovate, curved, yellow-brown, lid conic, apiculate;

peristome bryoid, endostome equally high, processes linear, cleft or perforated in middle. Male plant smaller, the infl. discoid, terminal, bracts very broad, obovate-lanc., nerved.

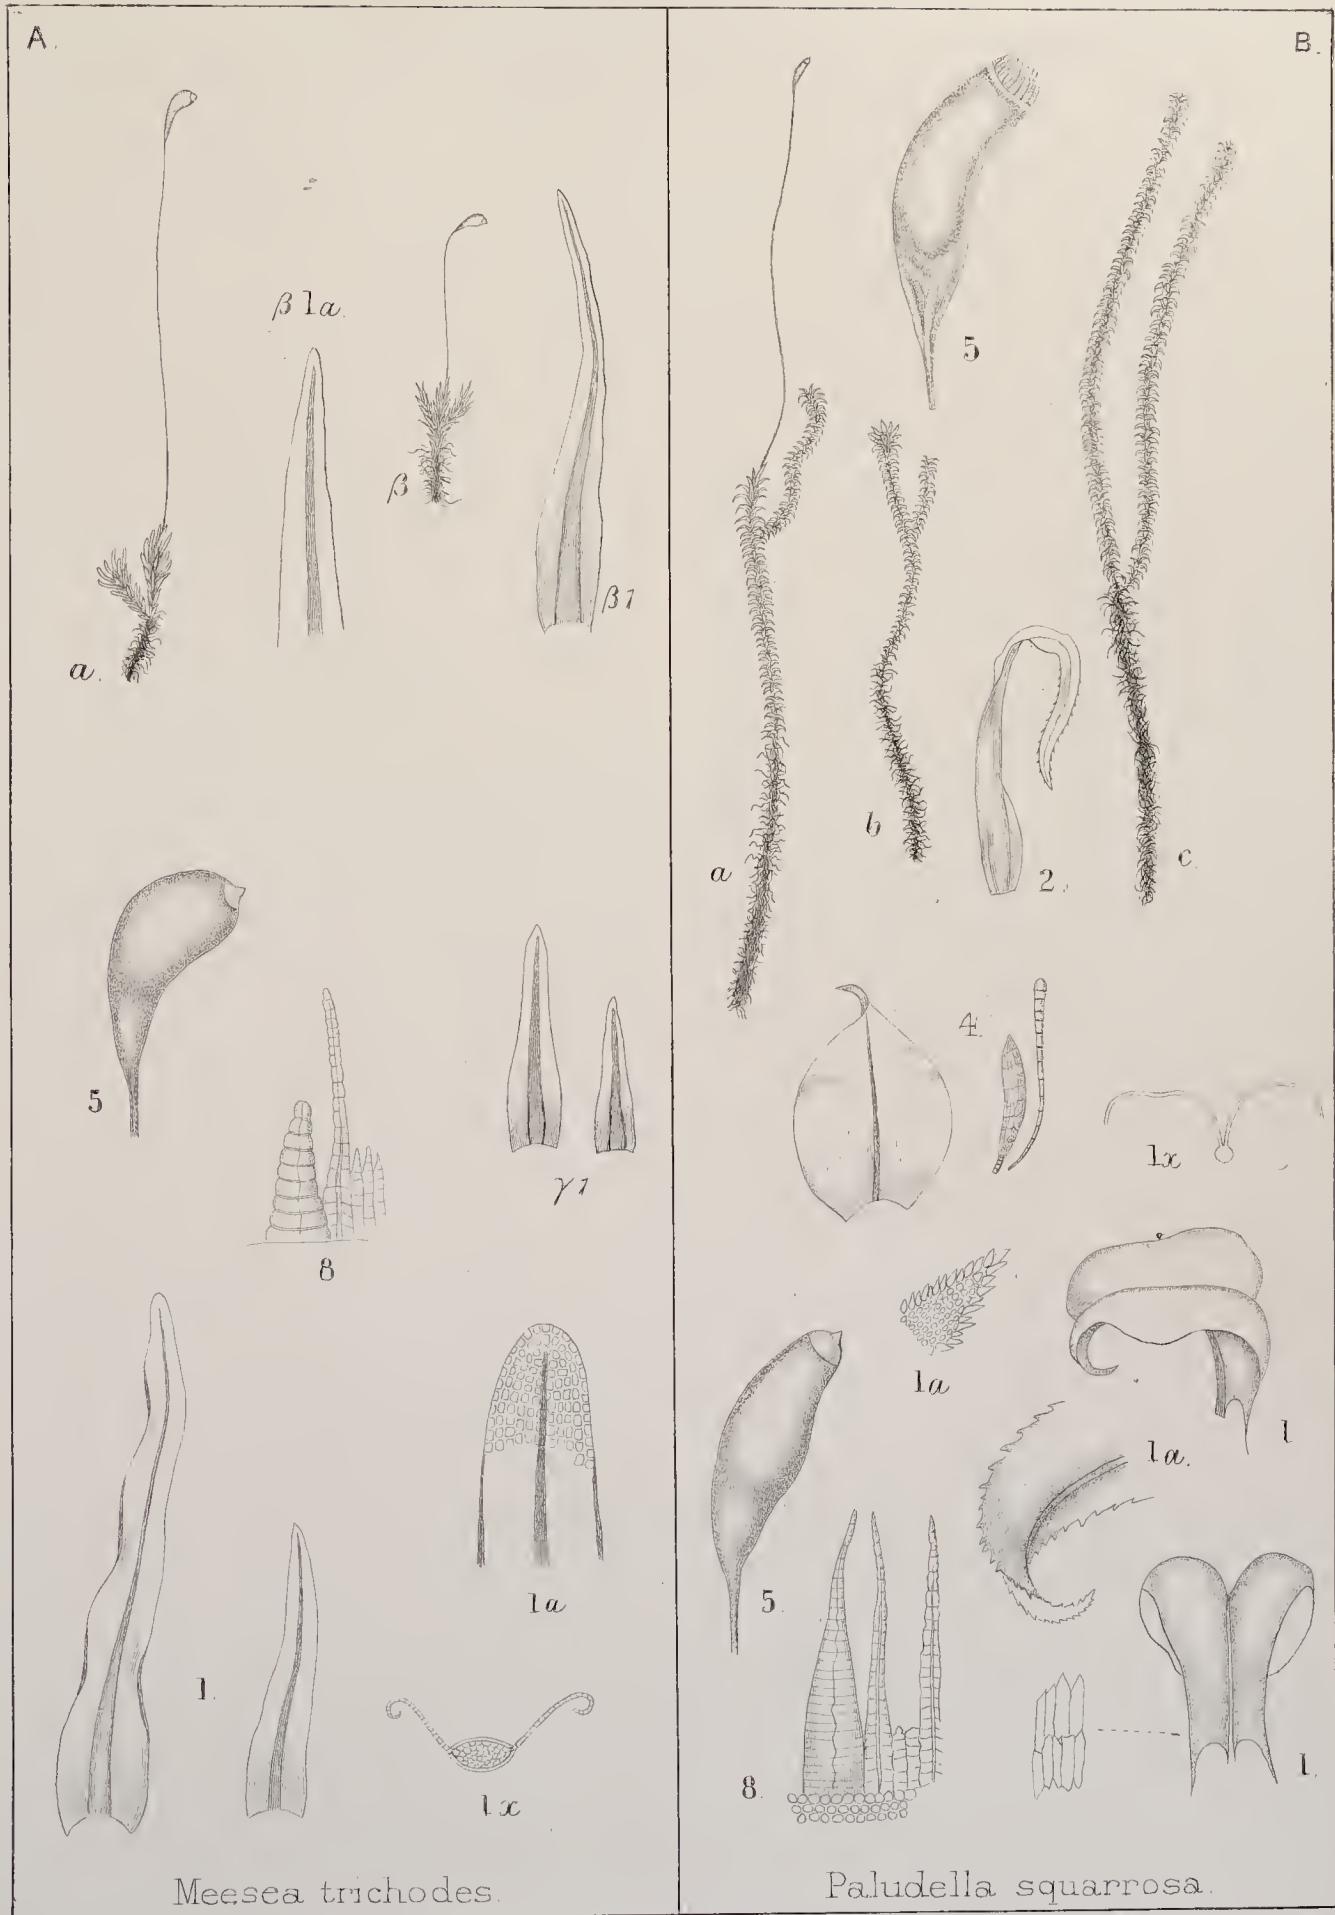

HAB.—Deep peat bogs, very rare and sterile. Fr. 6.

Knutsford moor, Cheshire (*Wilson* 1832)! Terrington Carr, Yorkshire (*Ibbotson* 1842)!!

This beautiful moss is now extinct in both localities. At Terrington it was plentiful and fully 6 in. high, but Mr. Slater informs me that in 1861 a deep drain was cut through the bog, and in 1868 he could only find a few stems not attaining more than 2 in. It has been reported as found on Ingleboro, but I have not been able to obtain any certain evidence as to the correctness of this record.

CINCLIDIUM SWARTZ.

Cinclidium stygium *Swartz.*

Fam. 18. MNIACEÆ.

Robust mosses, the stems generally tall and densely tomentose, with numerous branches or creeping stolons and flagella. Leaves large and accrescent upward into a coma, firm, broadly ovate, elliptic or lingulate, often with a thickened and dentate limb. Cells smooth or very rarely papillose, long and rectangular at base, rounded-hexagonal above, chlorophyllose or strongly incrassate. Capsule on a long rigid seta, often several in one perichaetium, longish-oval or subcylindric, cernuous; calyptra small, cucullate; peristome highly developed, bryoid. Male infl. terminal discoid. Inhabiting bogs, heathy ground and woodlands.

This fine family comprises about 100 species, and its fruit closely resembles that of *Bryum* but is more cylindric, and as in that genus the peristomes attain their highest development among the acrocarpous mosses. The genus *Rhizogonium* of some 30 species is almost entirely confined to the southern hemisphere and is remarkable for its basal fructification. Lindberg separates *Rhiz. microphyllum* as the genus *Trachycystis*, standing near *Orthopyxis* by its papillose leaves; *R. acanthoneuron* as *Leucolepis*, and *R. subbasilare* as *Goniobryum*, both having lax funarioid areolation as in *Amblyodon*.

Sect. 1. GYMNOCYBEÆ. Stem branched, often with slender sterile shoots or pseudopodia, which are leafless or bearing a few small scattered leaves below, and at apex a cluster of gemmæ. Leaves in 8 rows, cells small, each with a long papilla on both sides. Caps. oval or subcylindric, 8-striate, costate when dry.

1. GYMNOCYBE Fries.

St. agr. femsj, 27 (1825).

Bog mosses with the habit of *Dicranum Bergeri*, often bearing pseudopodia, naked or with undeveloped leaves. Leaves oblong-lanceolate, imbricated, the cells at base in 2—3 strata, large empty and pellucid, quadrato-rectangular, those above minute rounded, strongly incrassate, with trigonous interspaces and a large central papilla on each side. Capsule irregular oblique, teeth of peristome subulate, processes of endostome cleft in the keel, cilia 2—3. Male infl. discoid with clavate paraphyses.—Der. $\gamma\mu\nu\omega\varsigma$ naked, $\kappa\nu\beta\eta$ a head.

A small genus of three species, usually combined with the next, but differing in habit, in the andrœcium and leaf-structure, so that it is more convenient to keep them separate.

CLAVIS TO THE SPECIES.

Leaves erecto-patent, acute and serrate at point.
— imbricated, obtuse, entire.

palustris.
turgida.

I. **GYMNOCYBE PALUSTRIS (L.) Fries.**

Gymnoeybe turgida LINDB. in Not. ur saells. Faun. et Fl. fenn. foerh. ix, 85 (1867).

Sphaerocephalus turgidus LINDB. Musc. scand. 14 (1879).

Dioicous; in large yellowish-green tufts, readily falling asunder, yellowish-brown at base, not interwoven with tomentum. Stem 3—5 in. long, fragile, irregularly branched, thickened towards apex. Leaves imbricated, scarce decurrent, concave, longish obovate, broadly rounded, quite entire, reflexed at margin in lower half, incurved at apex; nerve thin, vanishing below apex, cells roundish, incrassate with a short papilla on each side, the basal in two strata, brownish, smooth, rectangular with some shorter rectangular green cells above them. Perich. bracts lanceolate. Caps. cernuous, ovate-oblong, symmetric curved, yellowish brown, 8-striate, lid conic, obtuse.

HAB.—Wet turf places in mountains, rare. Fr. 7.

Ben More of Dochart (*Prof. Barker* 1871). Whernside, Yorks. (*West and Lees* 1878)! Ben Challum, Perthshire (*Ewing and Binstead*)!! Creag Mhor, Perthshire (*Holmes* 1888)!! All sterile.

This plant is rarely found with fruit, and when this does occur as in Norway and Lapland, it is only found in small quantity. It might be confounded with the Var. *imbricata* of last species, but may be known by the larger size, absence of tomentum, and broader very obtuse leaves.

2. ORTHOPYXIS P. Beauv.

Prodr. p. 31 (1805).

Growing on sandy banks or rotten trunks of trees. With or without pseudopodia. Leaves entirely unistratose, with cells all of the same form, round, incrassate with a large central papilla on each side. Capsule regular, suberect. Male infl. gemmiform with filiform paraphyses.—Der. *oρθος* straight *πυξις* a capsule.

Our species is the only one found in Europe, a second *O. heterosticha* (HEDW.) P. BEAUV. occurs in N. America. The old authors mistook the gemmæ for male organs and this gave rise to the incorrect specific name.

ORTHOPYXIS ANDROGYNA (L.) P. Beauv.

Dioicous; leaves patent, narrow lanceolate. Capsule regular. (T. LXXX, C.)

SYN.—*Muscus capillaris omnium minimis foliis, pediculis, capitulis Vernonis* RAY Synops. 2 ed. 30, n. 10 (1696).

Sphaerocephalus androgynus LINDB. Not. ur Saells. Fauna Fl. fenn. foerh. ix, p. 41, Raett. och tillæg. (1867).

Dioicous; densely pulvinato-cæspitose, deep green above, ferruginous and tomentose at base, $\frac{1}{2}$ —2 in. high. Pseudopodia numerous, terminating in a globose head of elliptic gonidia, each of 2—4 cells. Leaves erecto-patent, linear-lanceolate, eroso-denticulate at apex, incurved when dry, margin reflexed in the lower half, nerve pale, vanishing and often flexuose towards apex; cells rounded, incrassate, with a papilla on each side. Perich. bracts lanceolate-subulate; caps. ferruginous, oblongo-cylindric, erect, then cernuous, when dry and deoperculate, horizontal, contracted, deeply sulcate; calyptra reaching middle of caps., long-beaked, lid large, convex at base, shortly conic; peristome very pale yellow. Male infl. terminal, gemmiform, bracts 12, linear-lanceolate.

HAB.—Woods and shaded gravelly banks. Fr. 6, very rare.

In fruit between Plumstead and Abbey Wood, Kent (*Dillenius*, Mitten 1843, *Braithwaite* 1854)!! now destroyed. Dunmore Tower, near Airth, Falkirk (*Lyle* 1849)! Valley of the Churnet, Stafford (*Dr. Fraser* 1868)!!

The numerous pseudopodia on this moss with their clusters of gemmæ, at once catch the eye, and no doubt afford a ready means for the increase of the species. It is extremely rare in Ireland; in Epping Forest it is frequent in hollows in the trunks of pollard hornbeams.

Sect. 2. TIMMIEÆ. Resembling *Polytrichum* in habit. Leaves from an appressed sheathing base, lanceolate, the cells small, hexagono-rotundate.

TIMMIA Hedw.

Stirp. cr. i, 83 (1787).

Stems simple, the leaves equal, sheathing at base, elongato-lanceolate, serrate. Caps. ovate-oblong with a short neck, not striate; calyptra small, cucullate, peristome as in *Mnium*.—Der. after J. C. Timm, of Malchin, in Mecklenburg.

A small genus of pretty mosses of which two other species are found in Europe, *T. megapolitana* and *bavarica*; all are very much alike in habit, which quite resembles that of *Polytrichum*.

CLAVIS TO THE SPECIES.

Leaf-base orange, widely sheathing, smooth at back.

— hyaline at insertion, scarcely sheathing, papillose at back.

austriaca.

norvegica.

1. **TIMMIA AUSTRIACA Hedw.**

Dioicous; leaves long, lanceolate, from an orange sheathing base above which the margin is inciso-serrate. Caps. ovate-oblong; cilia of endostome not appendiculate. (T. LXXX, D.)

SYN.—*Timmia austriaca* HEDW. Sp. musc. 176, t. 42, f. 1—7 (1801). BRID. Musc. rec. II, P. III, 155 (1803), Sp. musc. III, 98 (1817), Mant. 122 (1819), Bry. univ. ii, 71 (1827). WEB. MOHR Bot. Timmia polytrichoides β. *lutescens* BRID. Sp. musc. III, 99 (1817).

Timmia lutescens BRID. Bry. univ. II, 72 (1827).

Timmia megapolitana Var. β. HOOK. TAYL. Musc. br. 2 ed. 191, Suppl. t. 6 (1827). GREV. Scott. Cr. fl. vi, t. 326 (1828).

Dioicous; tall, robust, in rather dense tufts, yellowish green above, ferruginous at base. Leaves from a reddish brown sheathing base, suddenly lineal-lanceolate, rather glossy, erecto-patent, biplicate, when dry incumbent, subarcuate and convolute-concave above, the margin coarsely serrate, nerve serrate at back of the rather obtuse apex, cells linear at base, quadrate and incrassate above. Perich. bracts shorter; caps. horizontal, on a long seta, longish oval, reddish-brown, faintly striate, furrowed when dry; annulus broad, triple, lid orange-red, hemispherical with a small point; teeth yellowish-white, papillose, those of endostome not appendiculate. Male plant resembling the female, the leaves more divaricate, bracts patent.

HAB.—Rocks and stony places on mountains, very rare, sterile.

Rocks by the Isla, above Airly Castle, Forfarshire (Drummond 1824)! Ben Lawers (Wilson 1858)! Craig Mhor, Glen Lochay (Grieve 1888)!!

Timmia megapolitana HEDW. is smaller, autoicous, the leaf-base less sheathing and papillose at back, the processes of endostome with prickle-shaped appendages; it has been recorded from Ben Lawers, but all the specimens I have seen so named belong to the next species.

2. **TIMMIA NORVEGICA Zett.**

Dioicous; leaves not sheathing, having a band of thin hyaline cells at their insertion, serrate in the upper half. (T. LXXX, E.)

SYN.—*Timmia norvegica* ZETT. in Oefv. Vet.-Ak. Foerh. xix, 364 (1862), et in Bull. soc. bot. Fr. 1862, p. 288. SCHIMP. Synops. 2 ed. 526 (1876). JURATZ. Laubm. oester-ung. 335 (1882). HOBK. Timmia megapolitana $\beta.$ *norvegica* LINDB. in Oefv. Vet.-Ak. Foerh. 1864, p. 337.

Dioicous; in loose dark green tufts, fuscous at base, laxly interwoven with radicles and with hyaline paraphysiform hairs in the axils of the upper leaves. Leaves soft, scarcely sheathing circrato-crispate when dry, the upper long erect, yellowish-green, from an indistinctly sheathing yellow base, with a band of fragile hyaline cells at the insertion to the stem, gradually lineal-lanceolate, erecto-patent, short pointed, convolute-concave, shortly serrate in upper half of margin, indistinctly so below, cells in the lower half of leaf coarsely papillose at back, rectangular, upper hexagono-quadrata and papillose in front, nerve strong, reddish. Caps. horizontal, longish oval, lid reddish-yellow, with a very small point, inner peristome without appendages.

HAB.—On moist turf ground and mountain rocks, rare.

Ben Lawers (*McKinlay* 1866)!! Wood at south side of Powerscourt waterfall, Ireland (*D. Orr*).

The fruit has only been found in very small quantity, in three localities in the Tyrol.

Sect. 3. MNIEÆ. Plants tall, often with creeping stolons. Leaves large, with large smooth cells. Capsules oval or pyriform, pendulous, smooth.

MNIUM Dill. L.

Hist. musc. 229 (1741).

Fine showy mosses growing in damp shady ground, and under mountain rocks, usually innovating from the base of stem. Leaves large, especially in the coma, ovate, elliptic or spatulate; frequently with a thickened serrated limb, the cells parenchymatous, incrassate smooth. Capsule on a long rigid seta, pendulous or horizontal, oval, regular, calyptra small cucullate, peristome of 16 lanceolate cuspidate teeth, trabeculate externally, lamellose internally, endostome processes as long as peristome with 2—4 nodose cilia. Male infl. discoid with clavate paraphyses.—Der. $\mu\nu\iota\omega\sigma$ a moss.

About 50 species of this fine genus have been described, the greater part of which are natives of the north temperate zone. The peristome and endostome are both highly developed, and resemble those of the section

Eubryum. The distinction from *Bryum* depends on the habit of the plants and on the leaf-structure, the cells being very different from those of *Bryum*.

CLAVIS TO THE SPECIES.

Leaves with a thickened limb.	
Margin biserrate.	
Nerve vanishing below apex.	<i>hornum</i> .
— reaching apex.	
Synoicous.	<i>marginatum</i> .
Dioicous.	
Leaf-cells in oblique rows.	<i>spinosum</i> .
— not seriate.	
Leaves lax rufescent, with large cells.	<i>riparium</i> .
— dense green, with minute cells.	<i>orthorrhynchum</i> .
— serrate with solitary teeth.	
Synoicous.	
Lid convex.	<i>silvaticum</i> .
— rostrate.	<i>rostratum</i> .
Dioicous.	
Leaves broadly ovate.	
Marginal teeth spinulose, of 3 cells.	<i>cuspidatum</i> .
— obtuse, of 1 cell.	<i>Seligeri</i> .
— ligulate.	<i>undulatum</i> .
— entire.	
Synoicous, nerve vanishing.	<i>pseudopunctatum</i> .
Dioicous, nerved to apex.	<i>functatum</i> .
— not limbate.	
Leaves pointed, bluntly toothed by projecting cells.	<i>stellare</i> .
— obtuse, entire.	<i>cyclidioides</i> .

*Limb doubly serrate.

I. **MNIUM SPINOSUM** (*Voit*) Schwaeg.

Dioicous; in loose blackish-green tufts. Lowest leaves minute, squamiform, upper large, obovate cuspidate, the cells in oblique rows. Caps. oval-oblong, lid conic rostellate. (T. LXXXI, A.)

SYN.—*Bryum spinosum* Voit in STURM Deutsch. fl. II, 11 (1810). BRID. Mant. 119 (1819).

Mnium melanostomum BRID. MSS.

Astrophyllum spinosum LINDB. Musc. scand. 14 (1879).

Dioicous; robust, in very loose dingy or black-green tufts. Stems radiculose at base, blackish, often with 2—3 branches, dense-leaved subarcuate and flagelliform. Lowest leaves minute, squamiform,

obtuse, entire, scariose; upper large, patent, crisped and undulate when dry, obovate-spathulate, shortly cuspidate with the excurrent nerve which is rufous and serrate at back of apex, cells in oblique rows roundish-angular. Perich. bracts narrower, lanc., often enclosing several capsules, seta red, caps. horizontal or slightly inclined, oval-oblong, rufous brown; lid conic, obtusely rostellate: peristome reddish-brown, endostome orange. Male infl. large rosaceous.

HAB.—Pine woods and shady mountain rocks, very rare. Fr. 7.

Under rocks on Ben Lawers (*McKinlay* 1867)!! Glen Shee, Clova (*Fergusson* 1876).

A fine moss of somewhat rigid texture, and by no means attractive appearance owing to the dark dingy green colour. Only a few capsules have been found here.

2. **MNIUM MARGINATUM** (*Dicks.*) *P. Beauv.*

Synoicous; in loose bright green tufts. Leaves distant, decurrent, lower obovate-lanc., upper spathulate, limb bispinoso-serrate. Caps. ovate, shortly rostrate. (T. LXXXI, B.)

Dioicous; plants small, seldom above 1 in. high, lax-leaved, green, acquiring a rufescent or vinous tint, in loose tufts, the radical shoots more slender and elongated. Leaves slightly decurrent, distant, divergent, crumpled when dry, oval-lanceolate with a short point, limb red, of 2—3 rows of very narrow cells, with two rows of short blunt teeth nearly to the base; nerve red, ending in the point and faintly toothed at back, cells large roundish-angular, incrassate, about .015—.020 mm. in diameter, rectangular at base. Seta short, pale red, caps. cernuous, elliptic, pale brown; lid convex with a short beak, peristome greenish-yellow, endostome yellow.

HAB.—On stumps by shady banks of rivers and in woods, rare. Fr. 5.

Pondleigh stream, Hurstpierpoint (Mitten 1856)!! Mowthorpe Dale, Castle Howard (Spruce 1844)!! By a stream near Perth (R. Meldrum 1886)!!

This species has been confused with *M. orthorrhynchum*, by Wilson and others, even Lindberg ascribes minute areolation to *M. riparium* instead of to

the latter, and also erroneously refers *M. lycopodioides* to it. Like several other mosses growing by streams, it is liable to be covered by floods and hence charged with sand and dirt. It differs from *M. orthorrhynchum* in the colour and laxer areolation of the more distant leaves, and is altogether a smaller plant. The male and sterile specimens have alone been found here.

4. **MNIUM ORTHORRHYNCHUM** Br. Sch.

Dioicous; more robust. Leaves longer and narrower, dense, dull green, ovato-lanceolate, with two rows of teeth in upper half, minutely areolate. Capsule oval. (T. LXXXI, D.)

SYN.—*Mnium serratum* Var. β . SCHWAEG. Suppl. I, P. II, 129, t. 78 (1816).

Mnium serratum β . *Penninum* DE NOT. Syllab. 139 (1838).

Mnium marginatum β . *orthorrhynchum* HARTM. Skand. fl. 5 ed. 345 (1849).

Astrophyllum orthorrhynchum LINDB. Musc. scand. 14 (1879).

Dioicous; more robust, densely matted, dull green above, reddish at base. Stem taller, densely leafy. Leaves erecto-patent, ovato-lanceolate, the lower nearly entire, somewhat twisted when dry, limb narrow, doubly serrate in the upper half, nerve red, ending in the point, and serrate at back; cells not in rows, roundish-angular, .018—.025 mm. in diameter, strongly incrassate. Seta longer, red below, yellow above, caps. cernuous pale brown, oval, lid conic, shortly rostrate, peristome yellow-green. Male plants shorter with stout discoid many-bracted inflorescence.

HAB.—Wet rocks and stony places in limestone districts. Fr. 7.

Arncliff Clouder, Yorks. c. fr. (Nowell 1856) !! Ingleboro, on the Yoredale limestone at 2,000 ft. (Nowell 1858) !! Hazelden Gill (Hunt 1867) !! Litton Dale c. fr. (Whitehead and Ashton 1879) !! On elder stumps in a marsh at Pont Esgob, Hereford (Aug. Ley 1890) !! Lodore, Cumberland (Binstead 1889) !! Stock Ghyll force, Ambleside and Naddle Forest (Binstead 1893) !!

Taller, dense-leaved and more rigid than the last species, with much smaller areolation, and in habit resembling *Mnium hornum*.

5. **MNIUM HORNUM** L.

Dioicous; in dense dark green tufts. Leaves oblong-lanc., slightly decurrent, bispinoso-serrate, the nerve vanishing below apex. Caps. oblong-ovate, subpendulous, lid mamillate. (T. LXXXII, C.)

Bryum Polla horna BRID. Br. univ. i, 695 (1826).

Astrophyllum hornum LINDB. Musc. scand. 14 (1879).

Dioicous; densely cæspitose, 1—3 in. high, deep green above, reddish brown and tomentose at base. Stems simple, dense-leaved, erect. Leaves gradually accrescent upward, erecto-patent, slightly decurrent, somewhat twisted when dry, the lowest squamiform, entire at margin, median oval-oblong, upper oblongo-lanc., nerve ending below apex, serrate at back of apex, all acutely acuminate, limb and teeth rufous when old, the latter geminate; cells not seriate, rounded angular, perich. bracts narrow, lingulate-spathulate. Capsule on a long subflexuose purple seta, arcuate above, drooping and horizontal, oblong-ovate, yellowish-brown with a red mouth, lid convex with a pointed papilla; teeth of peristome pale greenish-yellow, endostome pale orange. Male plant shorter, infl. discoid, inner bracts broadly oval, ventricose, laxly areolate, suddenly acuminate, simply toothed.

HAB.—Damp shady banks and in woods, common. Fr. 5—6.

The swan's-neck curvature of the seta is a striking feature in the present plant, and the elegant peristome adds still more to its beauty; it is singularly free from variation, and in habit closely resembles *M. stellare*.

**Limb simply serrate.

6. MNIUM SILVATICUM Lindb.

Synoicous; fertile stem erect, simple. Leaves obovate, mucronate, comal ovato-lanceolate, simply serrate. Caps. ovate, subpendulous, lid convex. (T. LXXXI, E.)

Mnium silvaticum LINDB. in Not. ur Saells. Fn. et Fl. fenn. ix, 59 (1867).

Astrophyllum silvaticum LINDB. Musc. scand. 14 (1879).

Synoicous; simple, bright green above, strongly radiculose at base, with trailing and suberect shoots and subterranean stolons. Leaves decurrent, accrescent upward, undulate and crisped when dry, lowest obovate, entire, caudine erecto-patent, obovate, comal longer obovate-oblong, those of stolons rounded obovate, all ending in a mucronate point; nerve strong, smooth at back, ending before or in the point; limb of 3—5 series of unistratose cells, with solitary small yellowish teeth in the upper half. Leaf-cells not in rows, incrassate, roundish-oval. Caps. on a reddish-yellow seta, solitary oval subpendulous, pale ferruginous-brown; lid convex; peristome yellow, endostome orange, the processes widely lacunose, appendiculate, the basal membrane cribrose.

HAB.—Wet shady places in woods, on rocks and tree-roots. Fr. 4—5.

This species is not uncommon and is smaller than *M. cuspidatum* (L.) NECK. with which it was confused by the older authors, and from which it differs by the inflorescence and serrature of leaves. It is most frequent on limestone.

7. **MNIUM SELIGERI** *Juratz.*

Dioicous; erect, densely tomentose. Leaves lax, oval, longly decurrent, deflexed and convex above, teeth short, obtuse, of one cell. Caps. oval, pendulous, lid convex. (T. LXXXII, A.)

SYN.—*Mnium marginatum* SELIGER in Herb.

Mnium affine β . *elatum* BR. SCH. Bry. eur. fasc. 5, p. 31, t. 10, f. 2 (1838). HARTM. Skand. fl. 9 ed. ii, 29 (1864). C. MUELL. Synops. i, 159, p.p. (1848). SCHIMP. Synops. 388 (1860).

Mnium Seligeri JUR. MSS. LIMPR. in RABENH. D. kr. fl. Laubm. ii, 479 (1893).

Astrophyllum Seligeri LINDB. Musc. scand. 14 (1879).

Dioicous; in tall bright green soft tufts 3—4 in. high. Stem erect, densely coated with ferruginous tomentum, sterile shoots erect, lax-leaved. Stem leaves longly decurrent, decurved towards point and at sides so as to be convex, longish-oval, comal from a narrow base, oval-spatulate, with a short recurved point; limb of four rows of narrow cells, teeth solitary, pointing forwards, short obtuse, of one or rarely two cells, nerve excurrent in the point; cells in oblique rows, irregular, angular-roundish, with thick walls. Caps. pendulous, longish oval, usually solitary, lid orange, convex with a point, peristome pale yellow-green.

HAB.—Watery heaths and about springs. Fr. 5—6, rare.

Hell Kettles, Croft, Yorks. (Baker 1856)! Hale moss, Cheshire (Wilson 1858)!! Flitwick marsh, Beds. (Saunders 1888)!! Shap, Westmoreland (Binstead 1893)!!

This fine species is very close to *M. cuspidatum* L., but differs in habit, and the leaves are remarkably convex on the upper surface, from the bending down of the wings, the cells also having a lining of collenchyma, which swells by moisture and materially diminishes the cell-lumen, in which the chlorophyl usually runs together into bands lying free in the cavity. The true *M. insigne* MITT. is confined to North America, and it was by mistake he referred the Croft specimens to it in Hook. Journ. Bot. viii, 230.

8. **MNIUM CUSPIDATUM** (L.) Neck.

Dioicous; with long trailing shoots. Leaves roundish and obovate, slightly decurrent, with long sharp points; teeth long divergent, of three cells. Caps. oblong, pendulous, lid convex. (T. LXXXII, B.)

Another very closely allied species *M. medium* BR. SCH. is general in Europe and ought to be found here; it is synoicous and is nearest to *M. Seligeri*, but I find the utmost difficulty in discriminating the various forms; Limpricht retains *M. rugicum* as a fourth species, and certainly the leaf-margin differs widely from that of the type, the teeth when present corresponding to those of *M. Seligeri*, while the leaf-base and cells are those of *M. cuspidatum*. The variety *elatum* is scarcely more than a large form, with which *M. Seligeri* had been confused, and through it the marginal teeth gradually disappear until it passes into *rugicum*.

9. MNIUM UNDULATUM L.

Dioicous; tall, dendroid, widely cæspitant, deep green. Stem erect simple, with a number of branches arising from the rosette-like coma, which are flagelliform, dense-leaved and arcuate, and many strong horizontal stolons at base. Cauline leaves remote, oblong, comal elongate ligulate and decurrent, undulate, crisped when dry, limb of 3 rows of cells, confluent with the nerve at apex, simply serrate, leaf-cells irregular roundish. Capsules 2–10 in one perichaetium, cernuous, oblong, yellowish, becoming castaneous, annulus large, lid convex apiculate, peristome greenish yellow.

HAB.—Damp shady woods and hedge banks. Fr. 5.

This fine moss presents but little variation and is generally distributed, but the fruit is by no means frequent, when it does occur the number of capsules gives the plant a very handsome appearance.

10. **MNIUM ROSTRATUM** Schrad.

Synoicous; in loose trailing dark-green patches. Leaves large oval-oblong, obtuse or apiculate, bluntly toothed. Caps. oval, horizontal, lid rostrate. (T. LXXXI, F.)

Astrophyllum punctatum LINDB. Musc. scand. 13 (1879).

Dioicous; in loose tufts, dark green above, reddish below, with reddish-brown tomentum. Stems rigid, 1—3 in. high, with many erect shoots. Leaves distant, patulous and reflexed, upper 4—6 in a rosette, broadly obovate-spathulate, slightly emarginate and very minutely apiculate at apex, lower from a very narrow base, rounded obovate, limb rufescent, incrassate, cartilaginous, of 2—4 rows of incrassate cells, nerve purplish, ending abruptly below or in the point; leaf-cells angular-oval, highly chlorophyllose. Caps. horizontal or inclined, oval or ovate, yellowish-green becoming fuscescent; lid reddish-yellow, acutely rostrate; peristome yellow. Male plant more slender with fewer leaves.

HAB.—Wet rocks and sandy detritus of rivulets; common. Fr. 2—3.

Var. *β. elatum* Schimp.

Taller, more densely tufted. Leaves larger, thinner, with a narrower thinner limb, and without an apiculus.

SYN.—SCHIMP. Synops. 398, 2 ed. 489. LIMPR. op. c. 489.

HAB.—Bogs on the higher mountains.

Glen Callater (*Hunt*)!

Wilson had another variety which he named *cochlearifolium*, but the specimen I have seen differs in no way from the type, and the spoon-shape probably applies to the leaf in a growing state.

CINCLIDIUM Swartz.

SCHRAD. Journ. Bot. 1801, P. I, p. 25.

Plants tall resembling *Mnium punctatum*, interwoven with dense black tomentum. Leaves round, obovate, limbate, entire, cells hexagonal. Caps. pendulous, oblong; calyptra minute, cucullate, lid convex; peristome of 16 short obtuse incurved teeth, endostome a cupola-shaped membrane with 16 foramina opposite the teeth. Growing in spongy bogs.—Der. *κιγλις* a lattice.

A fine genus agreeing closely with *Mnium* in its vegetative system, but differing widely in the peristome and endostome, the latter forming a beautiful membranous dome supported on 16 pillars, between which the teeth curve inward. Besides our British species, *C. arcticum*, *subrotundum* and *hymenophyllum* are Scandinavian, and *C. latifolium* Siberian.

CINCLIDIUM STYGIUM Swartz.

Synoicous; in loose tufts, deep green above, reddish-brown at base. Leaves rounded-obovate, apiculate, limb opake, nerve subexcurent. Caps. pendulous, oval-pyriform, lid convex obtuse. (T. LXXXIII, D.)

Catharinea lateralis VAIZ. Ann. Bot. ii, 69 (1888).

Atrichum fertile NAWASCHIN in Hedwigia 1889, p. 359.

Paroicous or polyoicous; like *C. undulata*, but more slender and in looser tufts; the leaves more shortly acuminate and rather obtuse, lower distant, small and lingulate, upper suddenly larger, patent, the teeth at back smaller. At the centre of the terminal bud stand antheridia and bracts, and a row of archegonia encircle them, in others the two sets of organs are within separate bracts, and occasionally they are on separate plants. Fruit aggregated, 2—6 in the same coma, rarely solitary, seta straw-coloured, flexuose, caps. narrowly cylindric, straight or slightly curved, sub-erect, purplish becoming yellow-brown by age, lid purple with a subulate beak, nearly as long as capsule; peristome as in *C. undulata*.

HAB.—Damp shady banks, rare. Fr. 10—12.

On clay banks under beech trees near Broxbourne, Herts. (Vaizey 1886)!!

This plant is found in Siberia, Finland, South Norway, North Hungary and in the Bavarian alps, but only sparingly, and it has probably not been distinguished from the common species.

DITRICHUM ZONATUM (*Brid.*) *Limpf.*

Limprecht in his admirable "Laubmoose" i, 495, points out that this moss is distinct from *D. homomallum* and also from *D. nivale*, and is only known in

the sterile state; the 2nd, 5th and 6th synonyms in Br. Moss-flora i, 100, belonging to the latter species. *D. zonatum* is found on most of the higher mountains of the Breadalbane range.

DICRANUM UNDULATUM Ehrh.

Figured on T. LXXXIV, B.

Fine sterile specimens have been found in Dupplin woods and Woodhead wood, Perth (*R. H. Meldrum* 1891)!! It is best distinguished from *D. Bonjeani* by the divergent leaves, having coarse sharp teeth standing out from the margin, and both these have the leaf-cells shorter and not so narrow and linear as in *D. scoparium*.

TORTULACEÆ.

14.* MOLLIA BREVIFOLIA (*Sendtn.*) Braithw.

Dioicous; densely tufted. Leaves dense, from a lanceolate base, narrowly linear, obtuse. Caps. minute ovate; lid with a long very slender beak. (T. LXXXIV, D.)

SYN.—*Trichostomum brevifolium* SENDTN. in litt. C. MUELL. Synops. i, 572 (1849). LIMPR. in RABENH. D. kr. fl. Laubm. i, 575 (1888).

Dioicous; in densely cushioned tufts, fastigiate, dull green above, brown at base, the stems very slender, dense-leaved. Leaves short, from an erecto-patent base, slightly recurved, lanceolate, lineal and narrowed above, obtuse at point, the margins incurved, nerve yellowish, reaching apex or excurrent in an apiculus; cells at base minute rectangular, yellowish and transparent, above rounded-quadrate, opaque, papillose on both sides. Perich. bracts sheathing, acuminate with a projecting point, the cells thin rhombic smooth. Seta reddish below, yellow above. Caps. very small, erect, ovate with a narrow mouth, yellowish-brown; lid long as capsule, with a long very slender beak; peristome yellow, teeth longish, geminate, very slender, roughish. Male infl. gemmiform, terminal, the 3 inner bracts ovate, pointed, nerveless, toothed at margin.

HAB.—On rocks in limestone districts, rare. Fr. 6.

Upwey near Weymouth (*Mitten* 1885)!! Near Swanage, Dorset (*Mitten* 1890), both sterile.

This has probably been mistaken for *M. crisula*, but differs in the leaf, which is much shorter, and not boat-shaped at the apex.

9*. **BARBULA ICMADOPHILA** Schimp.

Dioicous; slender, in dense olivaceous tufts. Leaves ovato-lanceolate, acuminate with a long subulate excurrent nerve. Capsule subcylindric. (T. LXXXIV, E.)

SYN.—*Barbula icmadophila* SCHIMP. Bry. eur. fasc. 43, t. suppl. 2 (1850). Synops. 172 (1860), 2 ed. 211. C. MUELL. Synops. i, 614 (1849). MILDE Bry. siles. 117 (1869). JURATZ. Laubm. oest.-ung. 125 (1882). HUSN. Musc. gall. 106, t. 30 (1886). LIMPR. in RABENH. D. kr. fl. Laubm. i, 625 (1888).

Tortula icmadophila LINDB. de Tort. 249 (1864). DE NOT. Epilogo 553 (1869).

Barbula abbreviatifolia H. MUELL. in Verh. bot. Ver. Brandenb. 1866, p. 58.

Dioicous; in dense tufts, olivaceous green above, brown at base, the stems very slender, with short subcuspidate shoots. Leaves erecto-patent, from an ovate base, lanceolate, suddenly acuminate, the brownish nerve excurrent in a long subulate straight point about $\frac{1}{4}$ the length of leaf, margin revolute with a longitudinal fold just within it; cells uniform, incrassate quadrate, shortly rectangular at base. Perich. bracts longer, sheathing. Seta reddish, caps. brown, erect, almost cylindric, lid with a short oblique beak; peristome purple, twice twisted to the left.

HAB.—Moist alpine rocks; rare and sterile. Fr. 8.

Quiraing, Isle of Skye, and above Loch-na-Chat, Ben Lawers (Dixon, July, 1893) !!

This moss is very close to *B. acuta*, but has the leaves more suddenly narrowed above the middle, with the nerve much more excurrent. The fruit is very rare, but has been found at Krimmel fall, Salzburg.

CINCLIDOTUS.

2. **CINCLIDOTUS RIPARIUS** (Host) Arnott.

Dioicous; dull dark green. Leaves lingulate, obtuse with a short apiculus, scarcely keeled, limb of 5 rows of cells in several strata. Caps. exserted, longish, curved. (T. LXXXIV, C.)

SYN.—*Gymnostomum riparium* Host Syn. pl. austr. 563 (1797).

Trichostomum nigricans BRID. Sp. musc. I, 242 (1806).

Guembelia riparia C. MUELL. Synops. ii, 651 (1851).

Dioicous; in loose soft tufts, 1—3 in. high, dark green at apex, black at base, often with a metallic gloss. Leaves erecto-patent, when dry slightly incurved and twisted or incumbent, from a narrower base longish lingulate, obtuse with a short apiculus, scarcely keeled, nerve lost in the point or excurrent as the blunt apiculus and confluent with the thickened limb which consists of five rows of cells in 2—5 layers, the other cells smooth, rather small, dense and roundish. Seta about length of capsule, thick, orange; caps. exserted, longish oval, erect, somewhat curved, dark brown; calyptora conico-dimidiate, brownish, reaching middle of caps., lid conic, acuminate, incurved; peristome dark purple, the teeth irregular, in 2—4 smooth filiform legs, united at base by transverse bars. Male plant more slender and fasciculate.

HAB.—On stones in streams, very rare and sterile. Fr. 7—8.

River Fergus at Ennis, Co. Clare, Ireland (Stewart, July, 1884) !! In the Teme near Ludlow, Salop (Wayman 1890) !! Both sterile.

So closely does this moss resemble *Barbula mucronata* that it was long united with it, the *Barbula* being regarded as a terrestrial variety. In the barren state *B. mucronata* may be known by the leaves having the upper cells papillose, and the basal ones more or less transparent, and the margin revolute and of 2 layers of cells; in fruit the long red seta immediately distinguishes it.

BRYUM ALPINUM.

Var. γ . *viride* Husnot.

Tufts pale green, the leaves shorter, acute, with a few small teeth at apex, nerve yellowish, slightly excurrent.

SYN.—*Bryum alpinum* Var. *viride* HUSN. Musc. gall. 247.

HAB.—Banks of the Rattle brook, Dartmoor (*Holmes*) !!

BRYUM CAPILLARE.

Var. η . *elegans* Nees.

Tufts dense and soft, dull green above, ferruginous at base. Leaves dense, julaceously imbricated, very concave and spoon-shaped, broadly

oval, margin flat, narrowly limbate, nerve yellow, excurrent in a smooth recurved hair.

SYN.—*Bryum capillare* Var. *cochlearifolium* BRID. Bry. univ. i, 666. Bry. eur. fasc. 6-9, p. 61, t. 29 η. C. MUELL. Synops. SCHIMP. Synops. 372. MILDE Bry. siles.

CLASSIFIED LIST OF SPECIES.

Fam. 10. GRIMMIACEÆ.

- Subf. 1. *Grimmiææ.*
 - GRIMMIA Ehrh.
 - § 1. *Schistidium.*
 1. *G. conferta* Funck.
β. *pruinosa* Wils.
 2. *G. apocarpa* (L.) Hedw.
β. *alpicola* (Sw.)
γ. *rivularis* (Brid.) W. M.
δ. *gracilis* (Schleich.) W. M.
ε. *pumila* Schimp.
 3. *G. maritima* Turn.
§ 2. *Eugrimmia.*
 4. *G. anodon* Br. Sch.
 5. *G. crinita* Brid.
 6. *G. incurva* Schwaeg.
 7. *G. funalis* (Schwäg.) Schimp.
 8. *G. torquata* Hornsch.
 9. *G. Stirtoni* Schimp.
 10. *G. Muehlenbeckii* Schimp.
 11. *G. pulvinata* (L.) Sm.
β. *obtusa* (Brid.) Hueb.
 12. *G. orbicularis* Bruch.
 13. *G. trichophylla* Grev.
 14. *G. Hartmani* Schimp.
 15. *G. subsquarrosa* Wils.
β. *Edinensis* (Ferg.)
 16. *G. decipiens* (Schultz) Lindb.
β. *robusta* (Ferg.)
 17. *G. elatior* Bruch.
 18. *G. Donii* Sm.
β. *sudetica* (Spreng.)
 19. *G. alpestris* Schleich.
 20. *G. montana* B. S.
 21. *G. ovata* W. M.
 22. *G. ovalis* (Hedw.) Lindb.
β. *cylindrica* (Hsch.) Hueb.
 23. *G. elongata* Kaulf.
 24. *G. microcarpa* (Gmel.) Lindb.
 25. *G. campestris* Burch.

§ 3. *Dryptodon.*

- 26. *G. atrata* Mielich.
- 27. *G. unicolor* Hook.
- 28. *G. elliptica* (Turn.) Arn.
- 29. *G. patens* (Dicks.) B. S.

§ 4. *Trichostomum.*

- 30. *G. acicularis* (L.) C. M.
β. *denticulata* B. S.
- 31. *G. aquatica* (Brid.) C. M.
- 32. *G. obtusa* (Sm.) Lindb.
β. *subsimplex* Lindb.
- 33. *G. affinis* (Schleich.) Lindb.
β. *gracilescens* (B. S.) Lindb.
- 34. *G. heterosticha* (Hedw.) C. M.
- 35. *G. ramulosa* Lindb.
- 36. *G. fascicularis* (Schrad.) C. M.
- 37. *G. hypnooides* (L.) Lindb.
- 38. *G. canescens* (Timm) C. M.
β. *ericoides* (Schrad.) C. M.

COSCINODON Spreng.

- 1. *C. cibrosus* (Hedw.) Spruce.
- GLYPHOMITRIUM* Brid.
- 1. *G. Daviesii* (Dicks.) Brid.
 - 2. *G. polyphyllum* (Dicks.) Mitt.
 - 3. *G. saxicola* (W. M.) Mitt.

Subf. 2. *Orthotrichææ.*

ANECTANGIUM Hedw.

- 1. *A. Lapponicum* Hedw.
- 2. *A. Mougeotii* (Bruch) Lindb.

PLEUROZYGODON Lindb.

- 1. *P. æstivus* (Hedw.) Lindb.
β. *pellucidus* (Wils.)

ZYGODON Hk. T.

- 1. *Z. Stirtoni* Schimp.
- 2. *Z. viridissimus* (Dicks.) Brown.
β. *rupestris* Lind.
- 3. *Z. conoideus* (Dicks.) Hk. T.

4. *Z. Forsteri* (*Dicks.*) *Mitt.*
 5. *Z. gracilis* *Wils.*
- ORTHOTRICHUM *Hedw.*
- § 1. *Gymnophorus.*
1. *O. obtusifolium* *Schrad.*
 2. *O. rupestre* *Schleich.*
 - $\beta.$ *rupincola* (*Funck*) *Hueb.*
 - $\gamma.$ *Sturmii* (*Hsch.*) *Jur.*
 3. *O. Shawii* *Wils.*
 4. *O. affine* *Schrad.*
 - $\beta.$ *rivale* *Wils.*
 - $\gamma.$ *fastigiatum* (*Bruch*) *Hueb.*
 5. *O. speciosum* *Nees.*
 6. *O. striatum* (*L.*) *Hed.*
 7. *O. Lyellii* *Hk. T.*
- § 2. *Calyptoporus.*
8. *O. diaphanum* *Schrad.*
 9. *O. cupulatum* *Hoffm.*
 - $\beta.$ *nudum* *Dicks.*
 10. *O. anomalum* *Hedw.*
 - $\beta.$ *cylindricum* *Schimp.*
 11. *O. rivulare* *Turn.*
 12. *O. Sprucei* *Mont.*
 13. *O. stramineum* *Horns.*
 - $\beta.$ *patens* (*Bruch*) *Vent.*
 14. *O. Schimperi* *Hamm.*
 15. *O. pallens* *Bruch.*
 16. *O. tenellum* *Bruch.*
 17. *O. pulchellum* *Brunt.*
- WEISSIA *Ehrh.*
1. *W. Americana* (*P. Beauv.*) *Lindb.*
 2. *W. coarctata* (*P. B.*) *Lindb.*
 3. *W. Drummondii* (*Hk. Grev.*) *Lindb.*
 4. *W. Bruchii* (*Horns.*) *Lindb.*
 5. *W. ulophylla* *Ehrh.*
 - $\beta.$ *intermedia* (*Schimp.*)
 - $\gamma.$ *crispula* (*Bruch*) *Hamm.*
 6. *W. calvescens* (*Wils.*) *Braith.*
 7. *W. phyllantha* (*Brid.*) *Lindb.*
- Fam. 11. SCHISTOSTEGACEÆ.
- SCHISTOSTEGA *Mohr.*
1. *S. osmundacea* (*Dicks.*) *Mohr.*
- Fam. 12. SPLACHNACEÆ.
- SPLACHNUM *L.*
1. *S. ampullaceum* *L.*
 2. *S. vasculosum* *L.*
 3. *S. pedunculatum* (*Huds.*) *Lindb.*
 - $\beta.$ *sphaericum* *Swartz.*

- TETRAPLODON *B. S.*
1. *T. bryoides* (*Zoega*) *Lindb.*
 - $\beta.$ *Breweri* (*Hedw.*)
 2. *T. angustatus* (*Swartz*) *B. S.*
- TAYLORIA *Hook.*
1. *T. tenuis* (*Dicks.*) *Schöp.*
 2. *T. lingulata* (*Dicks.*) *Lindb.*
- Fam. 13. OEDIPODIACEÆ.
- OEDIPODIUM *Schw.*
1. *O. Griffithii* (*Dicks.*) *Schw.*
- Fam. 14. FUNARIACEÆ.
- Subf. 1. Discelieæ.
- DISCELIUM *Brid.*
1. *D. nudum* (*Dicks.*) *Brid.*
- Subf. 2. Amblyodontæ.
- AMBLYODON *P. B.*
1. *A. dealbatus* (*Dicks.*) *P. B.*
- Subf. 3. Funarieæ.
- NANOMITRIUM *Lindb.*
1. *N. tenerum* (*Bruch*) *Lindb.*
- PHYSCOMITRELLA *B. S.*
1. *P. patens* (*Hedw.*) *B. S.*
 - $\beta.$ *Lucasii* (*Nees Hsch.*) *Schimp.*
- PHYSCOMITRIUM *Brid.*
1. *P. sphæricum* (*Ludw.*) *Brid.*
 2. *P. pyriforme* (*L.*) *Brid.*
- FUNARIA *Schreb.*
- § 1. Entosthodon.
1. *F. obtusa* (*Dicks.*) *Lindb.*
 2. *F. fascicularis* (*Dicks.*) *Schöp.*
 3. *F. attenuata* (*Dicks.*) *Lindb.*
 4. *F. calcarea* *Wahlenb.*
 - $\beta.$ *patula* *B. S.*
 5. *F. microstoma* *B. S.*
 6. *F. hygrometrica* (*L.*) *Sibth.*
 - $\beta.$ *patula* *B. S.*
 - $\gamma.$ *calvescens* (*Schw.*) *Schöp.*
- Fam. 15. BRYACEÆ.
- Subf. 1. Oreadeæ.
- OREAS *Brid.*
1. *O. Mielichhoferi* (*Funck*) *Brid.*
 - $\beta.$ *compacta* (*Horns.*)

- Subf. 2. *Bryeæ.*
STABLERIA Lindb.
